User Stories: A user story is a statement of the desired functionality, from the perspective of a user. This desired functionality is aimed for user's benefit, but it may not be related to user's interaction with the system.

Criterion: Maturity

Use Cases: The notion of a use case was introduced in the middle of 1980s. There is established, experiential body of knowledge, for authoring 'high-quality' use cases, in form of guidelines (Cockburn, 2001), patterns (Adolph et al., 2003; Issa, Odeh, & Coward, 2006; Övergaard & Palmkvist, 2005), and anti-patterns (El-Attar, 2009; El-Attar & Miller, 2012). The relationship of use cases to concepts pertaining to other software artifacts, such as software architecture views, is established. It is common for use cases to be included in requirements engineering pedagogy, as suggested by recent textbooks on software engineering as well as on requirements engineering.

User Stories: The notion of a user story was introduced in the late 1990s. There is growing, yet undeveloped, experiential body of knowledge, for authoring 'high-quality' user stories, in form of 'smells' (Cohn, 2004), guidelines (Wallace, Raggett, & Aufgang, 2002; Cohn, 2004; Patel & Ramachandran, 2009), patterns (Leffingwell, 2011), and standards (ISO/IEC/IEEE, 2012). The

notion of a user story continues to evolve (Moreno & Yagüe, 2012). The possible types of stakeholders of a user story also continues to become granular and grow according to the needs of agile projects in different domains (Hochmüller, 2011; Read, Arreola, & Briggs, 2011). The inclusion of user stories in requirements engineering pedagogy is not common, although there are initial efforts in that direction (Fancott, Kamthan, & Shahmir, 2011).

The Framework in Context

The framework for comparison of use cases and user stories presented earlier uses a particular set of viewpoints. It could be noted that using a different set of viewpoints, or changing the framework itself, can lead to a comparison that has a possibly different outcome. For example, a business model, a cost model, or an organizational capability maturity model could serve as a basis for constructing alternative frameworks.

FUTURE RESEARCH DIRECTIONS

There are a few directions that emanate from the work presented in this article. These avenues are discussed briefly in the following.

The framework for comparison of use cases and user stories presented in this article has industrial implications. For example, the framework could be used as a basis for designing and conducting empirical studies (say, through surveys and/or interviews) of requirements engineering practices in organizations, including those organizations that are preparing for a transition from rigid to agile methodologies.

The framework also has pedagogical implications. For example, the framework could be used in a course on requirements engineering. This could be followed by feedback from students of their preference, if at all, of one type of agile requirement over the other (Fancott, Kamthan,

& Shahmir, 2011). The results obtained from an analysis of the feedback may help improve requirements engineering education, and is therefore of research interest.

The comparison of use cases and user stories carried out in this article is from the perspective of user stories. There are other entities in the requirements engineering body of knowledge that can also serve as possible candidates for a comparison with user stories. For example, such entities include 'conventional' software requirements defined by international standards, such as ISO/IEC/IEEE 29148 (ISO/IEC/IEEE, 2011). Indeed, such a comparison is important as agile methodologies continue to seek acceptance in 'conventional' software engineering contexts, as indicated by the latest version of the *Guide to the Business Analysis Body of Knowledge* (BABOK), the *Guide to the Project Management Body of Knowledge* (PMBOK), the *Guide to the Software Engineering Body of Knowledge* (SWE-BOK), and the *Kernel and Language for Software Engineering Methods* (Essence). Therefore, placing user stories in context of 'conventional' software requirements in a systematic manner, such as by using a framework for comparison as an instrument, is of research interest. It is evident that such framework for comparison will be different from that presented earlier, although certain elements of *Table 1* are likely to remain relevant.

CONCLUSION

The significance of requirements engineering in agile software development, and increasing to commitment to agile methodologies in the industry, necessitates a comparison of use cases and user stories. It is evident that an investment in software project artifacts, regardless of their type, entails costs. For example, such cost may incur from training the agile team, or from purchasing a management system. Therefore, or even otherwise, say, for the sake of requirements engineering education, it is important that such a comparison remain objective and accurate.

The framework for comparison presented in this article highlights both similarities and differences between use cases and user stories. From the comparison between use cases and user stories based on this framework, the following conclusion can be drawn. The use cases and user stories have different, albeit overlapping, goals, and different means of achieving those goals. Furthermore, they can co-exist and support each other. Indeed, it can be expected that the body of knowledge on use cases will continue to serve as a reference point for the development of the body of knowledge on user stories, thereby contributing to the advancement of agile requirements engineering.

KEY TERMS AND DEFINITIONS

Acceptance Criteria: The criteria that a system must satisfy in order to be accepted by a user, customer, or other authorized entity.

Agile Methodology: A software development methodology based on the Agile Manifesto. **Artifact:** A document or a model produced during software development.

Process: A set of interrelated or interacting activities that transforms inputs into outputs for some purpose.

Requirement: A statement which translates or expresses a need and its associated constraints and conditions.

Software Engineering: The application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, the application of engineering to software.

Stakeholder: An individual, team, organization, or classes thereof, having an interest in a system.

Use Case: A sequence of actions performed by a system, which yields an observable result of value to an actor of the system.

User: An individual who interacts with the software system usually, but not always, with a specific goal.

User Story: A high-level requirement statement that contains minimally sufficient information to produce a reasonable estimate of the effort to implement it.

INTRODUCTION

According to J. Spohrer, service-oriented systems are “value co-creation configurations of people, technology, internal and external service systems connected by value propositions, and shared information (such as language, laws, measures, models, and so on)” (Spohrer, 2007). A service-oriented system (Espadas et al., 2013) delivers a set of services that are cooperating with each other over the Internet, which are therefore called “web services”. Web services are delivered in a new computing paradigm called “service-oriented computing”. Service-oriented computing paradigm plays an increasingly crucial role in modern world industries. Even in cloud computing, services are irreplaceable elements (Wang & Sun, 2015). In service-oriented systems, software developers create software applications through composing web services. Web service composition helps developers to solve complex problems by combining published basic services and ordering them to meet specific service requirements from user requests (Song & Lee, 2013).

Service-oriented systems offer many benefits to software developers and software users. For example, they allow developers to support many customers with a single version of software and provide services to their customers 24/7. Over the past decade, a large number of service-oriented systems have been developed to aid a wide range

of real-world applications (Wang et al., 2011). For example, E-tourism service systems (see for example: www.visitcalifornia.com) have been used by tourists to plan their trip and book tickets as well as hotels. PayPal (www.paypal.co.uk), an online payment service, has been used by many e-commerce applications worldwide. Many investment banks or brokerages nowadays offer their customers trading services such as order management services, stock trading services, bond trading services and so on, and have been playing an increasingly pivotal role in the financial sector (Yang et al., 2011).

There are a lot of key research issues with regard to service-oriented systems, involving service modeling and specification (Cardoso et al., 2010; De Virgilio, 2010), service selection (Sweeney et al., 2016), web service composition algorithms (Hiel & Weigand, 2010; Leitner et al., 2010), verification of composition correctness (Rai et al., 2015), and handling composition faults (Lemos et al., 2016), etc. Rather than only concentrating on functionality, recent work puts more emphasis on Quality of Services (QoS) properties (Calheiros et al., 2015). With many businesses providing same or similar services, QoS properties have become an important indicator for good services (Zhao et al., 2007). Yet, satisfying QoS requirements in service-oriented systems has proved to be more challenging than satisfying functional requirements, due to the following characteristics (Yang

et al., 2011): First, QoS properties are system-level requirements which cannot be assigned directly to individual system components; instead, they need to be planned at the infrastructure-level as a whole, with their design aspects then entrusted to system components. Second, QoS properties are often interdependent and their realization in a system requires a collective and coordinated behavior of the system components and a system-level design strategy. Third, QoS properties are application-specific and their fulfillment necessarily requires a specific design approach germane to their applications. Finally, QoS properties are not only a design time concern, but also most crucially a runtime concern. Satisfying QoS properties means designing runtime mechanisms that can maintain the system's QoS properties throughout the execution time.

Through the investigation of several service-oriented systems in different sectors (Wang & Sun, 2015; Wang et al., 2011; Yang et al., 2011), this chapter has identified a core set of common QoS properties necessary for most service systems, which are performance, reliability and security. It is believed that these QoS properties are also universal to any service-oriented system. The aim of this chapter is therefore to provide an overview of these common QoS properties, give a precise definition of these QoS properties and offer an in-depth analysis of the issues, challenges and research opportunities of QoS properties in designing and developing service-oriented systems.

BACKGROUND

This section discusses existing research efforts related to QoS definitions and modeling, inter-dependencies among QoS properties and QoS technical support.

The Definitions and Modeling of QoS Properties

According to Zheng et al. (2014), QoS is a broad concept that encompasses a number of non-

functional properties such as price, availability, reliability, and reputation, so on and so forth. These properties apply both to stand-alone services and to composite services.

QoS modeling is a way to precisely define various QoS properties. There are also some QoS modeling approaches. For example, Bocciarelli and D'Ambrogio (2011) proposed an approach that extends Business Process Modeling Notations for modeling non-functional properties of business processes. This approach first constructed several meta-models to enable the modeling of multiple non-functional properties, such as performance, reliability and so on.

Non-functional Requirements (NFR) Framework, proposed by Chung et al. (2012), can be also considered as a way for QoS properties modeling. NFR framework treated non-functional requirements as “soft-goals”, and refined them to a set of fine-grained soft-goals and operationalization finally. i* (Horkoff et al., 2014) was a big improvement that integrates resources and tasks with goals and soft-goals, and defines four major types of relationships among them, which are resource dependency, task dependency, goal dependency and soft-goal dependency. With these four types of dependencies, the relationships between functional requirements and QoS properties were represented explicitly and much clearer. Besides, a QoS properties description model (Desai et al., 2005) was developed for QoS properties definition.

Inter-Dependencies Between QoS properties

There are numerous complex and nontrivial dependencies among quality properties, including *Conflicts* and *Cooperation* with different degrees, as described by Eyged and Grünbacher (2005). It is the same to QoS properties. A conflict occurs between two QoS properties if they make contradicting statements about common quality attributes or quality factors, whereas QoS properties cooperate if they mutually enforce common

quality attributes or quality factors. Quality Attribute Risk and Conflict Consultant (QARCC), designed by Boehm and In (1996), was an early attempt to investigate the conflicts between different QoS properties. Egyed and Grünbacher (2005) addressed the issue on false inter-dependencies, and proposed to use Requirement Tracing (RT) technique to filter out false conflicts and cooperation automatically. They determine whether two QoS properties have true dependencies according to the trace dependency between their related functional requirements. The dependency link is established depending on whether these functional requirements are overlapped. Take the e-commerce system for example, if the performance property “The system should give a response to users within 1 second when a user logs in the system” is constrained on the functional requirement “Login”, and another performance property “The system should give a response to users within 3 second when a user search the goods from the system” is constrained on the functional requirement “Search Goods”, then we can say these two QoS properties have false dependency since there is no overlap between their functional requirements “Login” and “Search Goods”.

Technical Support of Performance, Reliability and Security

Concurrency is mainly adopted to improve a service-oriented system’s performance. Tretola & Zimeo (2007) proposed a new technique, workflow fine-grained concurrency, to enable partially concurrent execution of some sequential activities in a workflow. Garcia et al. (2009) divided the whole application into a set of same application logics that are deployed onto different web servers, and used a QoS properties control mechanism to provide differentiation between distinct categories of service consumers.

Many approaches have been developed to support reliability, divided into two major categories: 1) sequential strategies, such as Retry (Chan et al., 2007) and Recovery Block (Scott et al., 2006),

which invoke backup services to take over primary ones when primary services fails; 2) parallel strategies, such as Active strategy (Salatge & Fabre, 2007), which employ multiple instances of services at the same time. Compared to sequential strategies, parallel strategies are more effective to enhance reliability through reducing failure rates, but parallel strategies consume more resources than sequential strategies and need to maintain the consistency among service instances all the time, which thereafter degrades the performance. Zheng & Lyu (2010) designed an adaptive QoS-aware middleware to provide reliable web services. This middleware dynamically selects sequential or parallel strategies according to user requirements and runtime QoS information.

Protecting messages from attacks is an effective way to support the confidentiality aspect of security. Rahaman & Schaad (2007) proposed an approach to avoid third-party rewriting by extending the message with an account section. OASIS also establishes a series of security specifications to improve the confidentiality of messages, such as Web Services Security (OASIS, 2012), Web Services Trust (OASIS, 2009), etc. In addition, service composition approaches also play a crucial role in supporting security for service-oriented systems (Koshutanski & Massacci, 2003). Secure service composition (Carminati et al., 2006) is to select services that satisfy client requirements by involving security concerns (i.e. confidentiality, authorization and authentication) into the composition process.

PERFORMANCE, RELIABILITY AND SECURITY

Three common QoS properties are discussed in this chapter, i.e. performance, reliability and security. Precise definitions to three common QoS properties and their detailed metrics will be first given as well as the real cases. Then the inter-dependencies between these QoS properties will be presented.

The Definitions and Metrics

Performance refers to the capability of service-oriented systems to achieve its functionality well. Performance can be measured by the system response time (Jayathilaka et al., 2015) and the system throughput (Yang et al., 2012). The response time of a service-oriented system is defined by the speed with which the service-oriented system responds to the customer request, whereas the throughput is defined by the number of results produced by the system at a set time.

Reliability usually refers to the probability that the system will conform to its expected behavior throughout a period of time. There exist different reliability models for different classes of systems. Some reliability models are based on the failure rate whereas others are based on the recovery rate. The most well known is the mean time to

failure (MTTF), which specifies the average time for which a system may be expected to function between failures. For example, if a service-oriented system is expected to have a failure rate of 10^{-3} failures/hour, its MTTF is once every 1000 hours. Reliability models that build on the recovery rate usually use the mean down time (MDT) to predict the reliability of a system.

Security refers to the capability of the system to protect information and data so that unauthorized persons or systems cannot read or modify them and authorized persons or systems are not denied to access them (ISO, 2001). Usually, security is not measured by a quantitative metric; instead, it is normally transformed into three types of specific requirements: authentication, authorization, and confidentiality. Authentication is the verification of the integrity of the data and of the identity of a party who generated the data. Authorization is

Figure 1. A summary of performance, reliability and security

the process by which one determines whether a principal is allowed to perform an operation, where as confidentiality is the protection of information from disclosure to those not intended to receive it (Reddy et al., 2014). Figure 1 shows a summary of the above QoS properties.

Examples in Industry Practices

A real-world service-oriented system – a Global Equity Trading System (GETS) is used to explain the above QoS properties. As a stock trading service system, GETS's main function is to facilitate its users to sell or buy shares online. GETS's users are traders and operators. Traders are investors who would buy or sell shares (also called orders in GETS) for their institutions or themselves, whereas operators are employees in stock exchanges who would use GETS to process shares. GETS is required to provide three major trading services for its users, which are Order Management, Trading, and Trade Management. Due to space limitation, only a few of QoS properties in GETS are presented as below. `

- **Performance**
 - Response time
 - The response time should be less than 5s during trading.
 - The response time should be less than 2s when placing a price to an order.
 - Throughput
 - More than 300 orders are matched per second.
- **Reliability**
 - Mean time to failure
 - The mean time to failure should be less than once every 10000 hours.
- **Security**
 - Authentication
 - Traders are required to login the system before submit an order.
 - Authorization

- Only operators can do trade management.
- Only traders can do order management.
- Confidentiality
 - Trade information should be sent to printing agents in privacy.

The Inter-Dependencies Between QoS Properties

QoS properties are not independent. Understanding the inter-dependencies between these QoS properties will facilitate a deeper understanding of each QoS property. A potential conflict and cooperation model is used to analyze the inter-dependencies between performance, reliability and security. This model is built on the basis of Egyed and Grünbacher's model (2005) as well as the experience of domain experts. The potential conflict and cooperation model is a two-dimensional matrix (*Table 1*), where rows represent affected QoS properties and columns represent affecting QoS properties. That means the value in each blank represents the potential effects that columns play on rows. To exactly specify the inter-dependencies between two QoS properties, the original potential conflict and cooperation model is adapted by extending the two-level effects to four-level effects, i.e. Make, Help, Hurt and Break. Make means two QoS properties strongly cooperate with each other, i.e. improving one QoS property will strongly increase another QoS property. Help means a low degree of cooperation, i.e. improving one QoS property will increase another QoS property. Break means there are strong conflicts between two QoS properties, i.e. improving one QoS property will strongly degrade another QoS property. Hurt means a low degree of conflict. For example, improving Security will strongly degrade Performance, thus "-" is filled in row 3, column 2. A typical example is checking user password. Checking user password is the design strategy for the security assurance, but this strategy will consume more time and accordingly the system

Table 1. The inter-dependencies between performance, reliability and security.

QoS Properties	Effect		
	Performance	Reliability	Security
Performance	++	-	--
Reliability	0	++	0
Security	-	+	++

Note: ++ represents Make; + represents Help; - represents Hurt; -- represents Break; 0 represents no effect.

will respond slowly to user's request, which makes contradicting statements with the performance. Improving Reliability plays no effect on Security, thus "0" is filled in row 2, column 4.

It is worth noting that the types of QoS properties can be changed according to the actual requirements of different systems. For example, the performance can be divided into two QoS metrics, i.e. response time and throughput, and re-evaluate the conflict and cooperation between these two QoS metrics and other QoS properties.

FUTURE RESEARCH DIRECTIONS

The development of service-oriented systems usually put emphasis on technologies at design and implementation phase, such as service modeling, service discovery, service composition, service evaluation, service monitoring and management. Yet, few considerations have been taken into the requirements analysis phase. It is widely recognized that the requirements of service-oriented systems are fundamental to execution of the subsequent development tasks. Likewise, ensuring the quality of service requirements is also a crucial but challenging task for service-oriented systems development. A service requirement specifies both the functional requirements and QoS properties for an atomic service or a composite service. The composition of services should follow contracts between different service providers, and contracts are derived from service requirements. It is believed that the modeling and analysis of

QoS properties will become more and more important in service-oriented systems development and the approaches or techniques to implement QoS properties modeling and analysis will be used more and more widely.

With regards to QoS properties modeling, there is still a lack of unified recognized classifications and definitions for various QoS properties, although a lot of classifications have been proposed. It is recommended that the classification and the definition of QoS properties should be towards a specific domain or a specific business sector, such as e-tourism systems, e-collaboration systems, and financial systems. In doing so, the modeling approaches of QoS properties will be more accepted and easier to applied in different areas.

With regards to QoS properties analysis, the techniques still remain at the qualitative analysis of inter-dependencies among QoS properties, whereas the quantitative analysis is rarely discussed. However, the quantitative analysis of inter-dependencies among QoS properties is crucial for the improvement of the whole system's quality. For example, to exactly which extent the security can affect the performance. Therefore, it is believed that one of the future research directions of QoS properties analysis is to put more attentions on the qualitative analysis of inter-dependencies among QoS properties.

CONCLUSION

Service-oriented computing is a promising computing paradigm for software applications. However, there are a lot of key research issues in the service-oriented computing paradigm, involving service modeling and specification, service selection, composition algorithms, handling composition faults, and so on. QoS properties are key factors to resolve these issues as well as a crucial aspect in the design of service-oriented systems because it directly touches the concerns of the service users. Therefore it is necessary and important to achieve a

deeper understanding of different types of QoS properties. This chapter introduces three QoS properties namely performance, reliability and security, and provides an overview of these QoS properties and offer an in-depth analysis of the issues, challenges and research opportunities of QoS properties in designing and developing service-oriented systems. It is hoped that through the demonstration and explanation, this chapter offers the readers an interesting snapshot of performance, reliability and security in service-oriented systems.

KEY TERMS AND DEFINITIONS

Performance: The capability of the service-oriented systems to achieve its functionality well, which can be measured by the throughput and the response time.

Quality of Services: The capability of the service-oriented systems to achieve its non-functional goals.

Reliability: The probability that the service-oriented system will conform to its expected behavior throughout a period of time.

Security: The capability of the system to protect information and data.

Service-Oriented Computing: A new computing paradigm that delivers services that are cooperating with each other over the Internet.

Service-Oriented System: A distributed software system based on the software delivery SaaS (Software as a Service) model.

Software as a Service: A software delivery model according to which a software vendor develops a web-based software application and then operates that application over the Internet for use by its customers.

Understanding User Experience

S**Camille Dickson-Deane***University of Melbourne, Australia***Hsin-Liang (Oliver) Chen***University of Massachusetts Boston, USA*

INTRODUCTION

As the need for information continues to drive the design and development process in society, understanding how one uses solutions is key. Interactions and the information they produce, drive how often and how successful an experience can be, knowing that each interaction may differ from another. User experience determines the quality of an interaction being used by an actor in order to achieve a specific outcome. The actor can have varying roles and evolving needs thus reviewing and predicting experiences are important. As an actor uses and gains feedback, the feedback guides individual and group behavior thus becoming pertinent to how interactions occur. This then questions how artefacts are designed to promote such interactions and what processes should be incorporated to ensure successful interpretation, use, physical reaction and conation. This chapter discusses the effects of user experiences today based on societal needs and expectations. It shows how the field is delineated into numerous sub-topics all of which can stand on their own yet, still draw from each other. The discussions will include fields such as cognitive science, human computer interaction, learning sciences and even ergonomics to show how design and subsequently interactions can assist in having successful user experiences.

BACKGROUND

User experience (UX) is defined as a generalised approach to acknowledging the quality of interac-

tion an actor [a user] has with an organisation, its service or products (Nielsen, 1992; Norman & Draper, 1986). This acknowledgement is defined as, but not limited to the actors' perceptual views, cognitive and affective feelings, interpretation of meaning, and attitudes. Today, UX is frequently known to review the quality of interaction an actor has with computer-related technology and is known to include an organisation or product's brand experience (Park, Han, & Kim, 2013). UX is identified as an action as well as a field with relational ties to several different knowledge brackets (i.e., Human Computer-Interaction (HCI), Ergonomics, Cognitive Science, Industrial Science, Human Factors) and has elements which include "usability, affect and user value" (McNamara & Kirakowski, 2006; Norman & Draper, 1986; Notess, 2001; Park et al., 2013 pg. 286; Tullis & Albert, 2008). As such, its history has varying starting points and thus varying influences (see Figure 1).

Norman (1986) known for his work in interaction design, first coined the term. The need to ensure that any experience an actor has with an object is classified not only by the expressed needs of the actor, but also by anticipating the future needs and thus uses of the said object [by the actor]. This means that an object can draw from many disciplines, in order to fulfil this expectation towards a satisfying experience for the actor. The UX is an outcome presented through the interaction of the actor with a user interface (Seow, 2005). The user interface is somewhat physical in its definition and typically describes the layer of an object where an action has an interaction to access

DOI: 10.4018/978-1-5225-2255-3.ch661

Figure 1. The Disciplines of User Experience Design. This figure illustrates the many disciplines which are included in the field of User Experience.

the said object. An example of the user interface, interaction and user experience is as follows

- **Actor:** A user (Man with no inherent challenges to using a door).
- **Object:** A door knob that is circular/round and smooth in design.
- **Context:** The user (the man) is aware of the time and is rushing to enter a law office before it closes. The entry to the law office

is a door with a door knob that is circular/round and smooth in design.

- **User Interface:** The surface of the door knob.
- **Interaction:** The user using their hand to grasp the door-knob with the intent of opening the door. The actions that may be included in the interaction are, turning, pushing, and pulling.
- **(Intended/Expected/Prior) User Experience:** The user based on previous experiences with other doors, turned and pulled the door knob to enter the law office.
- **[Actual] User Experience:** The user used the door knob, turned and pulled the door towards his/her person in an effort to enter the law office. The door provided feedback that it can only be pushed and as a result the user had to change their expectations and push the door.

The above example was elaborated to show how some of the complexity of the experience of opening a door can be for an actor (Dewey, 1925; Pucillo & Cascini, 2014). In this example, the mental model the actor had of the proposed experience of opening the door may have changed after the experience occurred. If there was a change between what was expected and what occurred, this means that the experience had by the actor differed from his/her own expectations and as a result, there are a number of feelings and misinterpretations occurred during the steps required for that one action (Pucillo & Cascini, 2014). This means that the user's experience with this system (i.e., man opening the law office's door), has to accommodate the actor's state; any previous experience including influences from professional practice; any additional properties that the system may have and finally the context in which the interaction will occur (Hassenzahl & Tractinsky, 2006; Lallemand, Gronier, & Koenig, 2015). When looking at what can be used to determine the steps in a user's experience, Pucillo and Cascini (2014) defined a framework

of affordances where a basic psychological action needs to be fulfilled (i.e., experience affordance), using physical and cognitive skills of the actor (i.e., use affordance), to manipulate an artefact (i.e., effect affordance) thus having some compatible interaction between the actor and the artefact (i.e., manipulation affordance). This experience that the actor has, is the result of his or her internal state (Dewey, 1925; Hassenzahl & Tractinsky, 2006 p. 95) and this state combined with the features of the designed system, the context in which the system was design and then the subsequent interaction that occurred creates for a spectrum of responses from the actor (Lallemand et al., 2015). A great example would be Shin, Jung and Chang's (2012) use of the Technology Acceptance Model (TAM) to test the intent of use for QR codes in the marketing of products. This research, showed that the quality of the QR codes influenced the user's perception of use through their own interaction with the artefacts (i.e., the QR codes). This further elaborates on Dewey's (1925) supposition that experiences are contextual to an individual and includes numerous factors such as emotions, expectations, interests and the like and as such [it] is a dynamic and temporary event.

The [user] experiences that currently occur are now referenced to computer screens and websites (Park et al., 2013). The ubiquitous use of portable technology in society means that the field that was once focused on the general use of objects and systems now is focused on technology-related objects and systems. Gross and Sheridan's (2011) study presented research on how students' used a university's library website. Their research focussed on the library's tool, *Summon* and found that most students showed positive experience with this new tool, and identified needed changes to assist students in evaluating retrieved information. In Kohler's (2011) research, he identified five research areas of pragmatism, sociability, usability, hedonism and collaboration as a virtual co-creation system, *Ideation Quest*, was researched to understand a users' co-creation experience. This research highlights not only the participants

experience in virtual worlds, but also illustrates where the experience seamlessly is modified into learning and performance behavior. These studies, reflect today's societal norms and now expands the discussion into other areas such as usability, learnability and accessibility (Park et al., 2013). Both of these terms, have great historical relevance to the field, even as we continue to exist in the Information Age. The meaning of usability and accessibility has changed because of the increase in societal use of technology and thus it means that UX design will accommodate many more pertinent discussions which will enhance the field.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

The importance of the user and their ability to access the information as provided, is key. This discussion needs to also include the conversion where the information retrieval experiences affect the learning process - thus allowing for *the user* to now become *the learner*. This broaches the boundaries towards ensuring that *the user experience* is also acknowledging *the learner experience* as well (Moore, Dickson-Deane, & Liu, 2014; Notess, 2001; Seow, 2005; Squires & Preece, 1996). The boundaries between the user and the learner experience is very much more prevalent in environments that are clearly demarcated for learning (i.e., online learning environments, environments associated with educational institutions, etc.). As technology is becoming more and more pervasive, the field of information science has blurred these lines and now encourages the sharing and collaboration of information not only with the intent to inform, but also for users to learn/perform (Moore et al., 2014; Notess, 2001; Squires & Preece, 1996). The field of user experience is exceedingly volatile due to the complex nature of the overarching fields (i.e., Human Computer Interaction) as well as the difficulty in use and interpretation of the topics needed to translate

conceptual concepts (Lallemand et al., 2015). Some of the concerns include:

- The importance of acknowledging that a user's experience, although being subjective to that individual and can also contribute to group behaviors.
- The knowledge that user's can learn bad behaviors from poorly designed solutions and that these bad designs should not diminish the power of a good design.
- That user testing should use the true "users" of the product and not short-change the value of the experience by testing others who can act like a user (i.e., "pseudo-users").
- A lack of awareness in understanding how to reduce the information-retrieval lag time yet enhance the experiences (i.e. information-access) of users.
- That accessibility of information and thus the experience does not mean that users need to be accommodated but is a cultural awareness that all users are to be included.

Thus, the experience is an encompassing realm, which affects the user through all of their senses and is demonstrated in design or usage through tangible and intangible objects, experiences and environments.

User Experience is Subjective but Affects Groups

UX is very subjective which when extrapolated affects a large number of individuals from any user-base. There are two views to a users' subjectivity which are beneficial for designers to understand

1. The act of finding objects in an interface and experiencing an environment or service is a very subjective activity (Glanz, 2012).
2. Accepting subjectivity as an ambiguous action but knowing that it is part of a group experience thus being an essential concept of user experience is important (Hassenzahl, 2010; Wright & McCarthy, 2010).

Law, Roto, Hassenzahl, Vermeeren, and Kort (2009, p. 726) provide a good example from their survey respondents, “only an individual can have an experience but I believe it can be externalised (albeit poorly) and recognised and related to by others,” to illustrate the relationship between “individual subjectivity” and “group”. Topics such as Open Educational Resources (OERs) and the design and access to such materials can sway entire groups away from the purpose due to poorly designed materials (Ives & Pringle, 2013; Rodriguez-Solano, 2015). This relationship is an important issue as researchers study user experience at the individual level, the group level, and the dynamics among the group especially as they are access information as well as learn using the materials being accessed.

Learning from Bad Designs

Another challenge with UX, is managing poorly designed interfaces. When interfaces are poorly designed, and the redesigned solutions provide more poor designs, there is a great chance that the user will learn and adapt their behaviors to accept the poor designs. Looking at a user’s behaviour over time can show that based on their own experiences, their behaviours adjust and sometimes accommodate and accept experiences which are not normally favorable (Hassenzahl et al., 2013; Karapanos, 2013). This creates a two-fold challenge for designers in that they

1. Should be cognizant of their design choices and really look for research to support their design choices.
2. Should research user behaviours over periods of time to illustrate continued usage and potential adoption and adaptability.

Using End-Users for Testing as Opposed to “Others”

One key challenge that occurs in user experience, is not using the end-users to obtain the true “user”

experience (Gruen, Rauch, & Redpath, 2002; Pruitt & Grudin, 2003). The key to getting the best feedback and seeing the value in the feedback is the reviewing of the experience using actual/potential users. Not using true end-users to gain the information needed on the experience can distort the *true* user experience thus hinder the design and development process (Shneiderman, 1998). Geelen, Reinders, and Keyson, (2013) emphasized that the involvement of end-users was critical to their study- design. In their study, they were able to identify needs, behavioral changes, and community initiatives of end-users to foster the design process instead of by technical and financial considerations. The value of end-user is well recognized by software engineers as the input from end-users improve software quality (Barker & Fiedler, 2012; Ko, Abraham, Beckwith, & Blackwell, 2011; Panko & Port, 2012). This is especially important where many UX projects are based on online environments and soliciting feedback from end-users can be easier to obtain (Hedegaard & Simonsen, 2013).

Challenges in Reducing Information-Retrieval Lag

Most design cycles rarely include the user experience and furthermore are not aware of the potential harmful lag has on the information retrieval process (Card, Moran, & Newell, 1983; Holden, Volda, Savoy, Jones, & Kulanthaivel, 2016). Liaw and Huang (2003) found direct relationship between the response time of the internet and a user’s perceived satisfaction. This relationship informed the user’s belief that the solution was easy to use, useful and addressed the core intent of the experience/use. Having an increased time in the retrieval of information is perceived to somewhat affect the user process negatively. The increased time can be internet access (i.e., insufficient bandwidth) or designs that force users to search for information that should be easily accessible (MacKenzie, 1992; Martin & Corl, 1986). When designing, considerations to Fitts’

Law (1954) and Hick-Hyman's Law is pertinent when looking at the user accessing information through computer interfaces. Fitt's (1954) Law discusses when a user attempts to select part of an interface, how quickly they can select that part of the interface is determined by the distance to the target and the size of the target. Hick-Hyman's Law describes the time it takes a user to make a decision as a result of the number of possible choices offered - increased choices is equal to an increased time (Seow, 2005). Both of these laws may not be readily used when determined how to manage user experience and be even more harmful during a learning activity (Moore et al., 2014). When discussing the design of a webpage, discussion on the information retrieval process is a given, but when designing online learning, this discussion tends to be coupled with other elements of the design process. Designing using online learning environments (OLEs) requires a more in depth approach – the designs are not only base on aesthetics but also include the meaning and thus correct interpretation of the content. This process of pedagogical usability, when elaborated also discusses [pedagogical] accessibility. Thus ignoring these key issues can negatively affect interactions (Bakaev & Avdeenko, 2015; Moore et al., 2014).

Accessibility and Usability

When usability was first defined, it focused on the effectiveness, efficiency and satisfaction of a product in a specific context (ISO 9241-11, 1998). Now as it is being redefined to include a user's emotional experience, the types of ways in which a product is used and access to the infrastructure and technology that provide the Internet (Bevan, Carter, & Harker, 2015) is highlighted. As usability continues to be addressed, accessibility is becoming just or even more important (Youngblood & Youngblood, 2013). Accessibility addresses a user's ability to have the same access, interact the same, and enjoy the benefit of the same services no matter their disposition (Section 508,

1998). Coupling both terms (i.e., accessibility and usability) is ideal for the user experience as they both are needed to sufficiently fulfil a user's experience. Being inclusive requires the specific attention to awareness of user characteristics and usage patterns. User's may have cognitive impairments that are not sufficiently disclosed before the user-testing process and this can create results which are not applicable to the tool but also results which are not inclusive to the potential user base.

SOLUTIONS AND RECOMMENDATIONS

UX design is somewhat secretly added to design and development cycles and even though it is a keen discussion with designers, organizations are yet to seriously include the concerns of the user into the general design process. Usability evaluations, if designed well, have many opportunities to capture user experiences and being aware of what an "experience" may really encompass is the most important part of the design and development process. Considering the individual characteristics, the true habits of a user, the differences in time-based experiences and the difference between access and usage will assist in solving some of the issues discussed. Using research to inform design decisions as well as recognising that the user is the initiator of the experience is the key to characterizing experiences and thus providing the impetus for solutions as needed.

FUTURE RESEARCH DIRECTIONS

Due to the numerous associated fields reflected in this chapter, future research directions may vary thus creating a great research field for *user experiences*. When dissecting *the user* and the characteristics associated with, current research includes the review of physical/behavioural attributes and now includes the cognitive attributes. Reviewing affective and now conative and social

abilities will be key going forward (Hilgard, 1980; Reeves, 2006). Some additional thoughts on future research include:

- **Human Factors and Ergonomics:** Technology is becoming smaller and more portable so looking at human well-being within the systems performance may raise issues with keeping up with technology usage. The age gap between those who know technology to be pertinent for their everyday existence and those who remembered when technology was not affordable, is growing. This means that there may be instances for researching physical injury associated with the newer technology designs, thus prompting more focus on the physical designs for everyday use; thus creating ties to accessibility and usability. This can also extend to include patient and doctors at hospitals – hospital records, admittance areas/computer-related forms, etc. All of these can address the support of functional and social health issues.
- **Cognitive Science:** In reviewing the virtual worlds and the immersive technologies, research can look at the field of gaming. The gaming industry has had a head start on what works for these environments but also extrapolating these experiences to simulated environments that can be used to train soldiers, doctors, emergency crew, new automobile drivers or simply a child learning to complete a messy activity in a safe environment, is an option. This also has other references to eye tracking studies and brain/cognitive mapping thus including design issues such as information retrieval and good design methods can assist.
- **Industrial Science:** Improving the quality and the productivity of any product is becoming easier from a user experience perspective. Technology is assisting industrial engineers in the observance of user behaviours and as smart cars and smart homes

are on the horizon, getting immediate feedback from users with varying characteristics to inform design and the use of such, will be one of the main foci.

- **Human Computer Interaction:** This field is heavily focused on the personalization and visualization of interactions. Future research may want to combine these two and push the observance review process to users (similar to the industrial science field) and allow users to illustrate their own personalized interactions thus informing a strategic push for informed personalized and personal designs.

Looking at the entire field of user experience and the future of the research, it seems like a good futuristic research will include, users as researchers/designers thus placing the control of the access, usability, quality and productivity in the hands of the product owner.

CONCLUSION

As the field of user experience continues to grow, so will the expectations of its use. Users are becoming more and more aware of the power they yield as a consumer and this means that they will more and more begin driving the design and development process. Being able to use social media to complain about or promote a product, provide feedback on experiences through recommender systems and even just be quietly observed through behaviour intelligence software is becoming the norm. Drawing more attention to the value of user experiences will in effect create additional sectors, which seek to use such influences to gain improvements on numerous offerings. Understanding not only the behaviours, thoughts and feelings that guide a users' experience, but also specifically looking at the decisions that are made as a result of all of these factors will influence the field of information science and definitely impact the learning.

KEY TERMS AND DEFINITIONS

Accessibility: Enables a person with a disability to be afforded the opportunity to acquire the same information, engage in the same interactions, and enjoy the same services as a person without a disability in an equally effective and equally integrated manner, with substantially equivalent ease of use (Section 508, 1998).

Affordance: The perception and actual properties which are used to determine the possibilities for actionable use.

Cognitive Science: A discipline that combines the study of the mind and its processes by building off of psychology, linguistics, philosophy, and computer modeling.

Interaction Design: A process where interfaces are created to promote behaviours that are influenced by users as well as influencing users at the same time. It allows for an observation of how users interact with user interfaces in an effort to learn user behaviour.

Usability: According to the ISO 9241(1998) standard usability is: “The ease with which a user can learn to operate, prepare inputs for, and interpret outputs of a system or component.”

User Experience: Sometimes referred to as UX is the subjective yet reactive occurrence an actor has when interacting with a company, its services and its products.

User Interface: A physical area which is used for communicating a user to a system. Due to the pervasive use of the technology, the definition is mostly used to define an information device which uses computer technology [system] as a medium to interact with a user.

The What, How, and When of Formal Methods

S

Aristides Dasso*Universidad Nacional de San Luis, Argentina***Ana Funes***Universidad Nacional de San Luis, Argentina*

INTRODUCTION

Formal Methods (FM) is an area of Software Engineering. They comprise a collection of methodologies and related tools, employing a mathematical basis –as do most engineering disciplines–, to construct its products. Although FM are part of Software Engineering, they extend their scope to the development not only of software products but also of hardware systems.

The goal of this article is to give answers to questions such as *what are Formal Methods*, *how are Formal Methods implemented*, *how are they used in Software Engineering*, *when should they be used*, among other related questions.

The chapter starts answering the question of *what are FM*; also the aims of FM are stated at the same time that their main characteristics are presented.

An example that shows *how* FM can be used to help specifying software requirements as well as the rest of the stages in a software development process is given as answers to the questions *how are FM implemented* and *how FM are used in Software Engineering*.

A discussion about *when they should be used*, explaining why they should be employed when the software system is required to be as secure and reliable as possible and how they can also be used as a complement to traditional development methods, is also provided.

A section on the state of the art in FM, providing an analysis of Lightweight FM and the grow-

ing impact that Model Checking is having in the software and hardware industry as an automatic FM for system verification, is presented. Finally, a discussion on the use of automatic analyzers like Alloy, which replace conventional analysis based in theorem proof by a “non-complete” analysis based in the examination of cases, is also given.

BACKGROUND

The ‘What’ of FM

What Are Formal Methods

FM contain a wide range of methods and related tools oriented to the production of secure and reliable software and hardware systems by employing a logic-mathematical basis.

As traditional development methods, FM consist of a set of techniques and supporting tools to assist developers during the whole software development process. The fundamental difference with traditional methods is that FM are based on mathematics and formal logic leading to unambiguous specifications, where desired properties of a system under development can be formally expressed and verified.

The adoption of FM makes possible the specification and the verification of software and hardware systems. They provide the mathematical tools to develop new concrete formal specifications and, eventually, executable code from abstract

formal specifications, where all the development steps can be formally verified.

Therefore, in contrast to traditional development methods, FM use mathematical proofs as a complement to software testing in order to verify the correctness of the system under development.

There are a number of different Formal Methods, each having its own notation, methodology and supporting tools; a comprehensive list of FM can be found in Formal Methods Wiki (Bowen). Formal notations or formal specification languages are used to produce formal specifications of software and hardware systems. There are different styles in formal notations, and there also are different degrees of rigor in development. Formal specifications can be written either using *abstract* or *concrete* style. Some formal specification languages adopt a *property-oriented* style, allowing the creation of *algebraic specifications*, where the desired properties of the system under development are given by axioms, in a purely declarative way. This kind of specifications is called *algebraic* because specifications are seen like heterogeneous algebras. A different style for specifications is the use of *model-based* notations, which make use of concrete data types (integers, reals, sets, list, etc.). They are more concrete than property-oriented specifications. However, in general, formal specification languages favors abstraction, being oriented to answer the question *what are the software requirements* of a system more than *how the requirements are going to be implemented*, i.e. they are oriented to describe what a system should do more than how it should be done.

Formality in the use of FM can go from the maximum degree of rigor, i.e. the use of formal specification and formal verification of the whole system to the use of formalizations for requirements specification only.

Some confusion can arise with the use of terms *formal language*, *formal notation*, *formal system* and *formal method*. In (Alagar, V. S. & Periyasami, K., 2011) the differences are clearly

stated. In Table 1 a synoptic view of the differences between those terms is shown.

A *formal notation* is a language that has both its *syntax* and *semantics* formally defined. Specification languages used in FM and programming languages are formally defined by their syntax and semantics. Syntax drives the validation of the language constructs. Strictly speaking the syntax of a language is given by the formal grammar of the language. There are a number of methods to do this, among them BNF (Backus – Naur Form). These methods are widely used to represent the syntax of programming languages, specification languages, etc.

Semantics, on the other hand, is a way of associating meanings to the language's valid constructs. Roughly speaking it can be said that given a language $\mathcal{L}$, the semantics of $\mathcal{L}$ can be represented by a pair $(\mathcal{U}, \mathcal{I})$, where $\mathcal{U}$ is the universe of values, i.e. the set of all possible values (numbers, characters, Boolean values, etc.), and $\mathcal{I} : \mathcal{L} \rightarrow \mathcal{U}$ is an interpretation function that assigns to each construct of the language $\mathcal{L}$ a value in the universe of values $\mathcal{U}$.

There are different styles for giving language semantics. *Operational semantics* is concrete; it may define an abstract machine, and is not well suited for proofs. In *Denotational semantics* a denotation (usually a mathematical object) is given to each phrase or construct of the language; since it is abstract, it is well suited for proofs; *Axiomatic semantics* is also abstract; here each phrase or

Table 1. A view of formal methods, formal systems and formal languages

Formal Method	Formal System	Formal Notation	Formal Language: formal syntax + formal semantics.
		Proof system; axioms + inference rules	
	Automatic tool support for specification, proof assistance, code generation, etc.		

construct of the language is described by axioms, and normally are limited to conditional equations.

As Table 1 shows, besides a formal notation normally implemented in a specification language defined by its formal syntax and semantics, a FM has also associated a *proof system* with its own *axioms* and *inference rules* that allows to produce formal deductions of system properties (theorems). These three elements make what is called a *formal system*.

Axioms are formulas of a formal system language that are considered valid. They are premises or ‘starting points’ for reasoning, using the deductive mechanism, in the formal system. *Inference rules* are syntactic rules or functions that given some premises return a conclusion. Together with the axioms of the formal system they can be used to infer new properties that are coherent with the axioms. An example of an inference rule is given in Equation 1. It states that, under the assumption that a logical expression E_1 has been proved true, then as a conclusion we have that a disjunction of E_1 with any other logical expression E_2 is also true.

Formal systems, which not only permit writing specifications but also proving formal properties of a system via their deductive mechanism, can be enriched with (a) techniques that guide the user on the steps to be followed during the development of a software system, going from the creation of abstract specifications that capture user’s requirements to more concrete specifications and eventually to an executable implementation, and (b) automatic tools giving support to these activities, namely edition, type checking, verification and translation to executable code. When all these conditions are met we can say that the formal system is a Formal Method.

Equation 1. Introduction of disjunction

$$\frac{E_1}{E_1 \vee E_2}$$

What Is To Be Done

The use of formal notations favors the writing of abstract specifications, focusing on the answer to the question *what is to be done* more than *how is to be done*.

This point is illustrated by a simple example of a queue specification. A queue is a very common data structure both in software and hardware, as well as in other areas of science. It is also known as one of the abstract data type (Black, 2014). It is a very common structure in everyday life as well, e.g. a queue of people at a teller’s window. A queue has a *front* and a *back* and it can be abstractly defined by the operations that can be applied on it: enqueue (add) when incorporating a new element in the queue; dequeue (remove) when taking an element of the queue out of it and first that returns the element at the front of the queue. Figure 1 shows a schematic of a queue.

Some rules must be observed when using a queue: No element can be removed from an empty queue, only the element in front can be removed, and a new element can only be added after the element at the back of a queue. This translates by saying that a queue is a FIFO structure: *First In First Out*.

In an abstract specification, it does not matter what a queue is holding, i.e. what kind of elements the queue has (e.g. people, cars, numbers, etc.), neither how the queue is implemented (by software, hardware, etc.), the important point is that a queue must respect the FIFO principle. Example 1 shows an abstract specification of a queue in RSL (The RAISE Language Group, 1992), the specification language of the RAISE formal method (The RAISE Method Group, 1995). RSL module QUEUE_0 defines two sorts (‘Queue’ and ‘Elem’); ‘Queue’ corresponds to the interest type of the specification and ‘Elem’ to the type of the queue’s elements. Both types have been specified as sorts, i.e. sets of abstract values with only one operator defined on them (the equality). **value** keyword introduces the definition of three functions and a constant, namely the functions

Figure 1. A schematic representation of a queue

‘add’ (enqueue a new element), ‘rem’ (remove or dequeue the first element), and ‘first’ (return the first element in the queue), and the constant ‘empty’, representing the empty queue. Both ‘rem’ and ‘first’ have been specified as partial functions ($\rightharpoonup$) since they are not defined for the empty queue.

Under the **axiom** keyword, the properties that a queue must hold have been stated; they specify the FIFO principle.

This specification does not say *how* the queue or its elements are implemented; it only specifies by means of algebraic definitions of its operations *what* the acceptable behavior of a queue should be. This is done by the axioms that combine the queue operations in such a way that the properties of a queue are clearly established. In the example, the first axiom establishes that the first element of a queue having only one element ‘e’ is element ‘e’; the second axiom establishes that the first element in a queue, obtained after inserting a new element, is equal to the first element in the queue before insertion, i.e. the insertion of a new element into the queue does not change the first element into the queue. The third axiom says that remove an element from the queue after adding a new one produces the same result that add the new element and then remove an element. Finally, the fourth establishes that a remove operation applied to a queue with one element empties the queue. This is an example of a *property-oriented* or *algebraic specification*, a kind of specifications that use sorts and algebraic definitions of functions.

The ‘How’ of FM

How to develop using FM? Traditional FM adhere to two different development approaches: *transformational* and *invent and verify*.

Transformational methods use a calculus; the developer starts from an initial abstract specification and following predefined and verified transformation rules obtain a new more concrete specification that preserves the properties of the initial specification. Successive calculations lead to new specifications and eventually to implementation.

In invent and verify approach, the developer starts with an initial abstract specification and in a successive step, ‘invent’ a more concrete specification that needs to be formally verified as an implementation of the previous one. This process can involve one or more steps until a concrete specification is obtained, which is suitable for translation to executable code. In this category is the RAISE method, which provides a “*refinement relation*” that can drive the development from an abstract specification to a concrete one. The formal definition of the refinement relation can be found in (The RAISE Method Group, 1995).

To illustrate the use of refinements, Example 2 gives a more concrete specification of a queue in the RSL module QUEUE_1, which can be formally proved as a possible implementation of the abstract specification given in QUEUE_0, i.e. one development step towards a more concrete specification of a queue has been ‘invented’.

Example 1. Property-oriented RSL specification of a queue

```

scheme QUEUE_0 =
class
  type
    Queue
    Elem
  value
    empty: Queue,
    add: Elem × Queue → Queue,
    rem: Queue  $\rightarrow$  Queue,
    first: Queue  $\rightarrow$  Elem
  axiom
     $\forall e: \text{Elem}, q: \text{Queue} \bullet$ 
      first(add (e, empty)  $\equiv$  e,
     $\forall e_1, e_2: \text{Elem}, q: \text{Queue} \bullet$ 
      first(add (e1, add(e2, q)))  $\equiv$ 
        first(add(e2, q)),
     $\forall e_1, e_2: \text{Elem}, q: \text{Queue} \bullet$ 
      rem(add(e1, add(e2, q)))  $\equiv$ 
        add(e1, rem(add(e2, q))),
     $\forall e: \text{Elem}, q: \text{Queue} \bullet$ 
      rem(add (e, empty)  $\equiv$  empty
end

```

Using the built-in types list (*) and **Nat** (natural numbers), type ‘Queue’ has been defined as a list of elements (Queue = Elem*) and the type ‘Elem’ as **Nat**. The signatures of the operations are the same. Now the axioms reflect the presence of built-in types and the use of some of its operations: **hd** (that returns the head of a list), and **tl** (that returns the tail of a list). Also the axioms now define explicitly the functions ‘add’, ‘rem’ and ‘first’, and the constant ‘empty’ (as the empty list) employing the operations of the RSL built-in types that were used for the implementation of the queue. Example 2 is also an example of a *model-based specification*, a kind of specification that makes use of concrete data types and explicit function definitions.

Examples 1 and 2 have clearly shown how different levels of abstraction can be achieved when writing formal specifications of a same problem. In QUEUE_0, an abstract, property-oriented RSL specification has been produced, where the proper-

ties that a queue must hold are given. In QUEUE_1, a more concrete, model-based specification has been created, as a possible implementation of the abstract specification.

To illustrate how a new development step (QUEUE_1, in the example) can be proved as an implementation of the previous one (QUEUE_0), the RAISE refinement relationship between these two specifications is informally described below:

QUEUE_1 is an implementation of QUEUE_0 if it satisfies the following two conditions:

1. The *static implementation relationship*, i.e. the signature of QUEUE_1 must include the signature of QUEUE_0. This means that all the entities (types, values, objects, variables and channels) in QUEUE_0 must be in QUEUE_1 with the same names and maximal types. This property can be checked statically by a tool.

Example 2. Model-based RSL specification of a queue

```

scheme QUEUE_1 =
class
  type
    Queue = Elem*
    Elem = Nat
  value
    empty: Queue,
    add: Elem × Queue → Queue,
    rem: Queue  $\tilde{\rightarrow}$  Queue,
    first: Queue  $\tilde{\rightarrow}$  Elem
  axiom
    empty  $\equiv$  <>,
     $\forall e: \text{Elem}, q: \text{Queue} \cdot$ 
      add(e, q)  $\equiv$  q ^ <e>,
     $\forall q: \text{Queue} \cdot \text{rem}(q) \equiv \mathbf{tl} \ q$ 
      pre q  $\neq$  empty,
     $\forall q: \text{Queue} \cdot \text{first}(q) \equiv \mathbf{hd} \ q$ 
      pre q  $\neq$  empty
end

```

2. The *preservation property*, i.e. all the properties in QUEUE_0 must hold in the refinement (QUEUE_1). Properties are expressed by means of axioms. They also include subtypes restrictions, constant and function's definitions and initial values of variables. The preservation property cannot be checked statically, it needs a formal proof.

In this example, the signatures of QUEUE_1 and QUEUE_0 are the same, namely same names and maximal types; therefore the static implementation relationship is satisfied. To prove the preservation property, we must prove that all the queue properties given by the axioms in QUEUE_0 hold also in QUEUE_1, i.e. the following *proof obligations* arise:

```

[ $\forall e: \text{Elem}, q: \text{Queue} \cdot \text{first}(\text{add}(e, \text{empty})) \equiv e$ ]
[ $\forall e1, e2: \text{Elem}, q: \text{Queue} \cdot \text{first}(\text{add}(e1, \text{add}(e2, q))) \equiv \text{first}(\text{add}(e2, q))$ ]
]

```

```

[ $\forall e1, e2: \text{Elem}, q: \text{Queue} \cdot$ 
  rem(add(e1, add(e2, q)))  $\equiv$  add(e1,
  rem(add(e2, q))) ]
[ $\forall e1, e2: \text{Elem}, q: \text{Queue} \cdot$ 
  rem(add(e1, empty))  $\equiv$  empty ]

```

There is a tool in the RAISE method that helps with the proof obligations. It provides help in proving whether going from one specification to another more concrete is a valid development step or, in other words, whether the more concrete one is a correct implementation of the previous one.

Another interesting *how-question* is *how a FM is constructed*? A FM is constructed from a number of elements, such as a logic, type theory and set theory. Additionally, a semantics, which is used in the definition of its specification language and that is closely associated with the underlying theory. The semantics and the syntax of the specification language conform the core of a FM. A theorem prover, with its methods and rules, and with different scope according to the theory chosen, is sometimes provided. Let us note that

not all FM count with theorem provers. Some of them have just a confidence checker based on type theory. Others FM do not rely on semi-automatic theorem provers for verification but on the use of fully automated tools like model-checkers or analyzers.

When to Use FM

Since the full application of FM requires highly trained and expensive experts, its use has not been widely spread. However, the application of FM is highly recommended mainly in the development of safety critical systems where minimal or zero tolerance to errors is mandatory. So, several organizations, among them the USA's Food and Drug Administration and NASA, all involved in medical devices, avionics, and other areas that require a high level of reliability in their systems, recommend employing FM in some form along the development of software and hardware systems.

Something important to point out in regard FM adoption is that its application does not release developers from testing. Testing and formal verification are complementary approaches. Not everything can be proved, as no testing can find all errors in a system. In addition, nevertheless FM is a useful tool for verification, some kind of validation of user requirements must precede a formal development as well as the delivered software. Therefore, an important recommendation when using formal development is testing all the produced software even if this has been subjected to formal proofs. Conversely, projects developed using traditional methods that have critical components can apply FM for the specification and verification of their critical components; hence, an integration of FM with traditional methods can be applied in these situations.

Finally, it is well-known that the use of mathematics is important in the development of error free products in engineering. It is true that a bridge that has been built using mathematics and physics can fall, but that is no excuse to avoid the use of engineering methods that are widely recognized

as providing assurance building. This idea and the problems associated to the costs of the application of traditional FM have motivated the searching for new ways of applying formality to various areas of system development. Two of the more popular ones are *Lightweight FM* and *Model Checking*, which are treated in the two following sections.

Lightweight Formal Methods

A crucial benefit, when using FM, is not only the possibility of writing unambiguous abstract specifications but more concrete specifications can also be given, and then proven by formal verification that a concrete specification is a correct implementation of an initial abstract specification, to finally obtain an executable piece of code from them; i.e. to prove that the desired system properties, given in an initial specification, still hold in the more concrete specification. Nonetheless, this activity is time consuming and expensive and the number of experts in the field is very limited.

However, although producing a full proof of a system from its initial formal specification is complicated and expensive, it is very useful in cases of critical system. To avoid FM drawbacks, other ways of using FM have been proposed.

One alternative is the adoption of *Lightweight FM*. Lightweight FM is the name given to the partial use of FM, for example when they are applied not to a whole system but only to its critical components (since they are particularly sensitive for reason of special requirements of reliability or security in the specification or in their verification). The partial application of FM for specification only, without formal verification is also referred as Lightweight FM.

Other ways of addressing this use of FM has been supported by new specific tools, analyzers that can generate instances of model invariants, simulate the executions of operations defined as part of the model and be able to check properties of the system.

One of these FM is Alloy (Jackson, 2012). Alloy proposes a new approach to FM, adopting the

use of a formal notation that is useful for describing structures, but that replace the conventional analysis based in theorem proving with the use of completely automatic tools.

An important difference of Alloy analyzer with formal theorem proof is that Alloy's analysis is not *complete* since the tool exams only a finite space of cases. However, the space of cases analyzed is usually counted in the billions or more cases, reaching coverages unreachable by testing. The analyzer, unlike testing, does not make use of testing cases; on the contrary, the user provides the properties that need to be proved.

Alloy has been used in a wide range of applications from finding holes in security mechanisms to designing telephone switching networks.

Using techniques that integrate FM with other more traditional methodologies or semiformal notations is also another way of Lightweight FM. There are a number of theoretical works that combine graphical notations with mathematically precise formalisms, such as providing formalism to the UML, either through the OCL language or by giving to UML graphic language a formal semantics – e.g. see (The precise UML group). Also there is much work done on formalizing Java and Java Machine –see (Hartel, P. and Moreau, L. A. V., Dec. 2001); (Bertelsen, 2003). Other good examples can be found in; (France, 1999); (Lano, 1991); (Weber, 1996); (William E. McUmbur and Betty H.C. Cheng, 2001); (DeLoach, S. and Hartrum, T., 2000); (Meyer, E. and Souquieres, J., 1999); (Funes, A. and George, C., 2003); (Hamann, 2015); (Reggio, G. and Larosa, M., 1997); (Gold-sack, S. and Kent, S., 1996); (Soon-Kyeong Kim and Carrington, D., 2000); (Amalio, N. et al., 2003), among others.

Model Checking

The correctness of the end result of a software development or hardware production can be verified in several ways. They all have to contrast the end product against some initial specification. The methods used to conduct the verification

differ in how the verification process is related to the specification. In general, the degree of user involvement and the completeness and soundness of the assertions that they allow to deduce is critical in determining the success of the verification.

In software as in other areas, a common verification technique is testing. In the case of software is impossible to achieve exhaustive testing. As previously stated, another important method that can be used in conjunction with testing is formal verification. A kind of formal verification is deductive verification where a correctness proof of a system specification is produced from the system axioms and inference rules provided by the underlying logic. This kind of verification is expensive and requires the presence of experts. An alternative to deductive verification is *Model Checking*.

Model Checking is a technique that is based on algorithmically verifying properties of a system. It permits verifying that a discrete model of a hardware or software system, which provides an abstract representation of his behavior usually given by a Kripke structure or a Label Transition System, satisfies some desired properties specified as formulas of a logic. The model of the system is specified in a formal language associated with the Model Checking tool, and the properties are usually given in a temporal or modal logic (Emerson, 1990), (Stirling, 1992). Temporal logics are formalisms that allow specifying properties like *reachability*, e.g. *Can we get to a system state where the formula ψ holds, by starting from the initial state?*

The birth of Model Checking can be attributed to Clarke et al (1986). In 1990, Model Checking received a significant enhancement by the publication of Burch et al (1990) of the symbolic model checking method.

There are a large number of tools available for Model Checking, free and commercial, which are proof of its wide use in software and hardware verification processes. A model-checker provides a completely automatic approach for proving that the system satisfies the desired properties. This

powerful assistance together with the existence of efficient model-checkers and expressive logics makes of model checking an attractive formal approach to software verification.

CONCLUSION

Whether FM are useful, whether FM should be used at all has been discussed for a long time. The importance that FM have in the developing of systems where security, reliability and safety are of the utmost importance, and the concern that these issues have in a number of standards and regulatory agencies and how FM plays a role in fulfilling these needs has been extensively discussed since several years ago, e.g. in (Bowen, J. and Hinchey, M., 1995a) (Bowen, J. and Hinchey, M., 1995b), (Bowen, J. and Hinchey, M., 1995a), (Bowen, J. and Hinchey, M., 2006), (Luqi and Goguen, J., 1997).

Their application in several fields of the industry and sensitive areas such as medical devices, space, avionics, hardware design and verification, and the use of other variants of FM, like Lightweight FM and Model Checking, is proof of its importance and usefulness in the development of critical and quality software.

In favor of this argument, the European Community (EC) has a project dedicated to FM, the DEPLOY Project (ICT- FP7-Deploy Project). In their site, they state that *their overall aim is to make major advances in engineering methods for dependable systems through the deployment of formal engineering methods*.

Kaivola et al. (2009) had replaced testing with formal verification in Intel i7 processor. In (M. Achutha KiranKumar V.), there is also a report on Intel using FM. Several other applications can be mentioned arguing in favor of FM, e.g. the Deploy project site holds pages dedicated to Success Stories of the application of FM (ICT-FP7-DEPLOY Success Stories) and on the use of FM in industry (ICT-FP7-FM).

The main benefits of FM must be found in creating unambiguous specifications and the associated facility of formally proving system properties. All this is facilitated by an underlying logic with a set of axioms, rules and tools, which are part of FM. This constitutes an assurance in the quality of the developed system. These advantages are not present in traditional development systems, where there is no formal semantics for their notations and, consequently, their specifications can suffer from ambiguities and contradictions.

However, we cannot elude the drawbacks of FM. FM rely on the fact that their successful application is based on the involvement of algebra and mathematical logic experts able to conduct correctness proofs, making FM adoption hard and expensive. We cannot also elude the fact that formal specifications can complicate the communication with end users, making the requirement validation difficult. In this regard, a graphical notation, although not formal, is perceived as more intuitive and facilitates communication with non-experts. In fact, there is a great deal of effort put into creating tools and methods that combine FM with more traditional development methods, e.g. by integrating graphical notations with formal semantics.

FUTURE RESEARCH DIRECTIONS

Judging by the important concepts and theoretical results that FM research activities have provided to Software Engineering and that are nowadays in use, such as abstract data-types, pre- and post-conditions, symbolic evaluation, invariants, runtime assertions, state-space analysis, and many others, it is to be expected that in the future FM will continue with its significant contributions.

An analysis of the main currently ongoing research conferences dealing with FM, the scope of the subjects and the number of researches in the area can be used as example of the strength and vitality of the FM area and also serve as an

indicator of the research directions that the field is undertaking. The main interests are directed to:

- *Research into hybrid approaches to formal modeling and analysis; i.e., the combination of (formal and semi-formal) methods for system development, regarding both modeling and analysis.* iFM 2016, URL: <http://en.ru.is/ifm/> (Retrieved march 2016).
- *Addressing critical problems faced by the modern railway – how to deliver reliable service to passengers and to freight operators, while maintaining very high levels of safety. So what can be done? Techniques and tools are needed for modelling, analysis, verification and validation that can cope with the new more complex systems; these techniques must support rather than impede the development process and must address and ensure: Required functionality, Safety and integrity, System security, Adherence to standards.* RSSR 2016, URL: <http://conferences.ncl.ac.uk/rssrail/> (Retrieved march 2016).
- *Developing and evaluating systems that interact with physical processes, and systems that use artificial intelligence technology. Examples include autonomous systems, robots, and cyber-physical systems in general. Applying formal methods to these systems of growing interest and importance is challenging because they exhibit much greater non-determinism than traditional systems, making them challenging to assure.* FM 2016, <http://www.fmeurope.org/?p=567> (Retrieved march 2016).
- *Temporal representation and reasoning in (1) Artificial Intelligence, (2) Databases and (3) Logic and Verification.* TIME 2016, URL: <http://time2016.compute.dtu.dk/index.html> (Retrieved march 2016).
- *Theories of computation and programming, foundations of software engineering and formal techniques in software design and verification, as well as tools that sup-*

port formal techniques for system modeling, design and verification. ICTAC 2016, URL: <http://cc.ee.ntu.edu.tw/~ictac2016> (Retrieved march 2016).

- Symbolic and state space-based techniques for the validation and analysis of software systems. Techniques and empirical evaluations based on explicit representations of state spaces, as implemented in the SPIN model checker or other tools, or techniques based on the combination of explicit representations with other representations, are the focus of this symposium. SPIN 2016, URL: <http://www.spin2016.info/#> (Retrieved march 2016).
- Formal methods and advanced software technologies, especially for engineering complex, large-scale artifacts like cyber-physical systems, networks of things, enterprise systems, or cloud-based services. Contributions relating to formal methods or integrating them with software engineering, as well as papers advancing scalability or widening the scope of rigorous methods to new design goals are especially welcome. KEY TERMS AND DEFINITIONS

Algebraic Specification: Formal specification given in an abstract style based in the use of sorts and algebraic function definitions, like in heterogeneous algebras (multiple sets and their operations).

Formal Proof: Finite sequence of well formed sentences of a formal language, where each sentence either is an axiom or it follows from the previous sentences derived using a rule of inference; the last sentence is the assertion to be proved (theorem).

Model-Based Specification: Formal specification using concrete types and explicit function definitions.

Proof System: Provides a way of deducing formulae, beginning with the axioms of the logic and using its rules of inference.

Property-Oriented Specification: Formal specification given in an abstract style, where the system behavior is defined by a set of properties. These properties are given by axioms relating functions and sorts. (See Algebraic Specification).

Semantics: In a language, it is the meaning of a valid syntactical element, as opposed to syntax, which describes how the symbols of the language are combined to form valid constructions. Most programming languages have their syntax defined formally (traditionally in BNF), while formal specification languages have also their semantics defined formally.

Specification: A document describing what a system should do, what a problem is or what a domain is all about. In formal methods this document is written using a formal language.

Verification: The process of determining whether a product fulfills a set of previously established requirements. In formal verification, this is the process of proving that a more concrete specification preserves the properties of a more abstract specification.

INTRODUCTION

Citizens today are connecting through social media and consuming more digital content than ever before (Sasseen, et al., 2013). There are nearly 300 new applications being created every day and, according to the Massachusetts Institute of Technology, more than 10 new groundbreaking technologies created every year (2015). These new apps are placed into the app store (Vaala, Ly & Levine, 2015) with little regulation on “educational value” to help educators choose apps that are, in fact, educational as determined by the science of learning (Hirsch-Pasek, et al., 2015).

Though most know our technologically-rich society requires a more technologically-literate educator, teacher preparation has not yet caught up with this reality. There are many reasons for this gap: dwindling higher education budgets that make continually updating technology difficult; preservice students coming into teacher preparation programs with varying competencies and understandings of appropriate technology use (Carroll & Morrell, 2006); and teacher preparation/education faculty members who may have little competence with emerging technologies (Polly et al., 2010).

In order to support preservice teachers (PTs) in developing competency in technology integration we make four suggestions—PTs must:

- Become knowledgeable about what developmentally appropriate practice looks, feels, and sounds like (NAEYC, 2009);
- Explore and develop knowledge about ways experts authentically utilize technologies to consume, create, and connect in their areas of expertise;
- Engage in hands-on experiences with a range of technologies across content areas to build their level of comfort; and,
- Demonstrate their competency in integrating technology with content in developmentally appropriate ways.

This chapter provides a framework for how we construct this foundational understanding with PTs. It shares exemplars-in-practice, and suggests needed changes in order to support this practice across institutions of higher education.

BACKGROUND

We utilize the Technological Pedagogical Content Knowledge (TPACK) framework (Figure 1, Mishra & Koehler, 2006) as a theoretical lens for our argument. TPACK represents one (of many) useful models for thinking about specific knowledge teachers must have to effectively and meaningfully integrate technologies into their

instruction. Every lens and model has its shortcomings and/or pitfalls (Schmidt, et al., 2009), but we selected TPACK because its compartmentalization and overlapping of three main pieces—Content Knowledge, Technical Knowledge, and Pedagogical Knowledge—are relevant given the ways in which American sets of standards for teacher preparation and student achievement have parsed out content knowledge as a distinct part of teaching and learning and have integrated pedagogy and technology into their standards. The framework holds the most effective way to integrate technology is for teachers to simultaneously draw on their technological, pedagogical, and content knowledge.

The TPACK model has been successfully applied to inservice teacher training (Hutchison & Woodward, 2014; Niess, 2011) and has been used to explore the growth and development of PT's application of technology in P-12 classrooms as well

(Koh & Divaharan, 2011; Pamuk, 2011). Studies of TPACK have suggested (1) it is difficult to affect change in PTs' technological content knowledge (Hofer & Grandgenett, 2012); (2) higher TPK scores were apparent in lesson plans associated with models of teaching with which they had the most familiarity as learners themselves (Lee, et al., 2014); and (3) technology-infused approaches to teacher preparation yielded more rapid increases in CK and PK, thus impacting the depth of the PT's understanding of the content as well as the ways in which the methods/pedagogy are effective to support content area learning.

The ways in which the school-aged students will be required to utilize the technology impact the requirements for teacher preparation. In America, the Common Core State Standards (National Governors Association Center & Council of Chief State School Officers, 2010) drive the integration of technology/digital components in reading, writ-

ing, language, and speaking & listening (Hoffman, et al., 2014) in many states. Here, the idea is that *all* professions utilize reading, writing, language, and speaking & listening to accomplish their work. Some young children come to school with informal and play-based experiences (Marsh, et al., 2015; Plowman, 2012) in operating a range of devices, coding, digital composition, gaming, viewing, digital reading, online researching so it is imperative that PTs understand these funds of knowledge young children may bring to formal learning contexts.

In order to become a licensed teacher in America, PTs are to demonstrate competency of a range of technology standards (see Council of Chief State School Officers, 2011). In these standards, “technology” is broadly mentioned four times: as a tool for assessment and differentiation; as a support for content and skill development; as a tool for accessing, interpreting, evaluating, and applying information; and as a subject of study (i.e. digital citizenship).

In university-based teacher preparation and certification, coursework often includes a stand-alone course (carrying 1-4 credit hours) in which PTs evaluate and apply technology to content-area lessons. Some institutions integrate technology into their methods blocks as well (and with somewhat encouraging results [Wetzel, et al., 2014]). So, while the TPACK framework (Figure 1) is useful for thinking about what knowledge teachers must have to effectively and meaningfully integrate technologies into their instruction, we suggest teacher preparation programs might take it a step further through applying constructivist theories (Dewey, 1938; Malaguzzi, 1993) of teaching and learning.

TECHNOLOGY INTEGRATION AS A PRESERVICE COMPETENCY

This section presents three components of technology integration in PT coursework that work to unpack the developmental appropriateness of

technology and pull broadly on elements of socio-constructivist pedagogies. These components allow PTs room for exploration, tinkering, and talking about the technologies while learning how they can be utilized as tools to consume, create, or connect people across space and time.

The inspiration for these components is rooted in the Reggio Emilia Approach (REA). The Reggio Emilia schools (in Italy) have a well-known and respected approach that values learners as strong and capable individuals who are co-learners alongside their teachers (Edwards, Gandini, & Forman, 2012). The REA suggests learning takes place through the exploration of many “languages of learning,” referring to the different ways learners construct knowledge of the world around them. Technologies are simply another language/tool for learning.

We encourage and support teacher preparation faculty in becoming familiar with and utilizing technology resources to support their own practice. If faculty are not proficient in at least some technology it is very difficult for them to support appropriate use of technology with PTs and they may be reluctant to use technology or to expose their lack of knowledge to their students. To counter this, Polly and colleagues (2010) present a framework in which faculty are given time to work with the technology themselves and learn from knowledgeable faculty or even students in order to support them in taking risks by incorporating technology into their own teaching.

Third, we require PTs to actually practice technology both as a tool for carrying out their professional work and for teaching content (Puerling & Fowler, 2014; Wetzel, et al., 2014). In this way, the PT is engaged in real-life, culturally important, hands-on experiences in which he or she seeks to construct understanding about the world around him/her--two features of developmentally appropriate practice (NAEYC, 2009). Our PTs are tasked with utilizing technology for personal communication and productivity, entertainment, socialization, research, assessment, and teaching (among other things).

SOLUTIONS AND RECOMMENDATIONS

The following exemplars-in-practice are used to illustrate how our PT programs start to intentionally and systematically support PTs' construction of TPACK knowledge (presented in Figure 1) by utilizing the REA. Our PTs: (1) explore how professionals authentically use technology; (2) build their own background knowledge about a wide range of hardware, devices, and software; and (3) tinker with technology across diverse content and with myriad pedagogical approaches in preservice preparation. In these ways, a socio-constructivist lens overlays onto the TPACK framework.

Exploring Authentic Use of Technology Across Professions

In the foundational courses of teacher preparation, faculty utilize concept-mapping as a strategy to document what PTs know about a range of professions. They view a video clip that was intended to teach children about a profession (the pediatrician field trip on *Mr. Rogers' Neighborhood*) and consult online reading material ("Doctors" on PebbleGo.com; e-how articles). After watching the clip, faculty models for and guides PTs through mapping out who, what, where, why, and how each profession is carried out.

An essential component of the 'how' part of the concept-maps involves looking at the technology utilized in each profession and its relationship to the professional's end goal. Traditional paper and markers are utilized for thinking through one of the explored professions, but other mapping software are presented at each station/profession (Poplet, Mindmup [see example, Figure 2], Explain Everything, etc.) and then the software are replicated on multiple devices (computer with wired/wireless mouse, iPad, iPod Touch; laptop). For example, the PTs might explore how:

- A scientist uses a microscope to zoom in, captures the image with a screenshot, and

uses overlay/annotations to document their findings;

- A doctor utilizes some low-tech technologies (otoscope) to determine health and documents findings on an electronic medical record (see computer-based mapping example, Figure 2);
- A journalist uses multiple outlets to communicate their messages and connect to others (oral or written news interviews, podcasts, twitter or other social media, documentaries);
- A musician uses sound mixing software to record and edit a track.

In this example, the technology/media (video-based media clips and a range of software designed for mapping), content (social studies related to community workers/jobs), and the faculty's modeling of pedagogy (modeled and shared experiences with the technology, guided practice to try it out, and independent practice) are integral components that support the PT's development in multiple areas of the TPACK framework, applying a constructivist approach.

Building Background Knowledge About Technology

As indicated in the above example, faculty seamlessly weaves in the range of hardware, devices, and software into the guided practice/exploration component of the lessons. Access, guided exploration, and intentional use of a range of technologies and media ensures that PTs are able to build and construct their background knowledge about the affordances and limitations of each piece of hardware or software.

PTs engage in backchannel discussions (through Twitter, Padlet, and/or a Today's Meet applet embedded into our course learning management system) to document their connections, questions, and thoughts related to course content. PTs utilize Twitter to access readings/news articles related to education and young children and then

Figure 2. Map of “pediatrician” using Mindmup application on a computer

they engage in a backchannel conversation using a hash tag to easily communicate with the group. As an extension and a meaningful way to connect to practical uses of these tools in early education contexts, PTs view and discuss a video of a classroom of first graders engaged in this process as their teacher reads aloud (Harvey et al., 2013).

Trying it out in multiple ways contributes to the PT's understandings of the affordances and constraints of each hardware and software. The PTs then relate those to theories of child development, pedagogical knowledge, and content knowledge in order to determine whether the technology might be useful to augment, modify, or redefine the child's learning process (Puentedura, 2015).

Tinkering While Learning How to Teach

A socio-constructivist view of learning involves constructing knowledge through language-facilitated social experiences (Vygotsky, 1978). For PTs to be prepared to incorporate technology into their classrooms it is less important to 'train' them how to use a specific piece of hardware or software than it is to practice engaging with unfamiliar or newly emerging hardware and software with the mindset to determine the affordances and drawbacks as related to a particular student/class of children. PTs who become comfortable with the process of tinkering to construct knowledge

about these tools are much better able to use them with intention and also to approach unfamiliar technology in the future with more confidence. Some examples of how PTs have tinkered with the technology for various purposes through their preservice programs follow (see also Wilkinson & Petrich, 2013).

Consuming New Information and Supporting Exploration of the World Around

Identifying and consuming new information represents one viable method of acquiring the answers to the inquiries that occur during learning. People from nearly all professions now consume new information from electronic resources—news-papers/magazines; online encyclopedias, wikis, and journals; e-books; online tutorials; and PDF files. These are all used to research and acquire new information about the world around (Pew Research Center, 2014). In the real world, people harness technology to acquire and consume large amounts of new information. When their search strategies are effective (Henry, 2006), they can end up with visual, printed, and audio forms of information on just about any topic.

And, while the reality of “the real world” exists, a large disconnect remains between how people in “the real world” find and consume their information, and the “school world” parallel experience. For example, most PT preparation programs do not require teachers to purchase digital textbooks, yet classrooms as young as Kindergarten and first grade are utilizing digital textbooks for students in multiple content areas (see <http://www.discoveryeducation.com/>, for an example). Moreover, it is far less common to see early childhood teachers reading aloud from an e-book than it is to see them reading from a printed text (Roskos, 2013). To help bridge this gap and to learn through a more constructivist lens, PTs engage in several hands-on experiences.

First, PTs read a PDF version of a children’s book and use the comment and annotate tools

in the program to document their connections, questions, predictions, and vocabulary learning. Next, PTs utilize a web-based electronic version of a children’s chapter book (<http://www.wenovel.com/tag/Charlotte-s-Web.html>) and a web annotation applet (<https://www.diigo.com/index>) to extend the digital reading experience to another device. After, PTs explore a third children’s title using an e-reader application and the built-in text annotation tools. PTs are required to share their text on a projection screen (link from their own device to the teacher podium), and conduct a read aloud of a section of one of the books to the class, thinking aloud about their navigation through the digital text in addition to their comprehension or vocabulary focus. After the three e-reading experiences, we tinker with sharing out our annotations with others in the class via social media outlets.

As a second way to build knowledge about consuming information through electronic sources, PTs tinker with searching for various kinds of information through hash tags on Twitter, Pinterest boards for science experiment ideas, YouTube videos to build playlists for “virtual field trips” (Blachowicz & Obrochta, 2005), conventional library-based searches, and even exploring how different search engines yield different kinds of information on the same key search terms.

As a part of learning about being a good consumer of digitally packaged texts, PTs tinker with at least 5-10 different applications in their methods courses and discuss the quality of the software and identify risks to children (apps with advertising, links to social networks, requesting private information). PTs arrive at the conclusion that the software ranges from inaccurate and distracting to thoughtfully designed and engaging (Hoffman & Paciga, 2014; Paciga & Hoffman, 2014; Schuler, 2012). They are introduced to the position statement on technology use in early education, (NAEYC & Fred Rogers Center, 2012), Common Sense Media (n.d.), and *Children’s Technology Review* (n.d.) as ways to help determine the level of developmental appropriateness of software, apps, and media for their students; our claim is

not that “all PTs need to know THESE resources,” but, rather, that PTs should become familiar with these *kinds* of resources in order to best support their teaching.

Connecting and Communicating Through Technology

In addition to consuming new information with technology, PTs can benefit from tinkering with technology to (1) connect to others and (2) share their messages to those in their networks. In their professional lives, teachers might connect and communicate for a couple of purposes exemplified in the following paragraphs—to communicate daily happenings with parents and other stakeholders, and to communicate a child’s achievements and interests to parents or guardians.

The practical uses of technology can enhance the teachers’ ability to connect (Paciga, 2016). When considering teaching and learning from an REA perspective, one area of pedagogical practice where this connection is very clear is in working with parents and families, as parents and families are considered co-learners alongside their children. For this reason, we consider it especially prudent for PTs to be prepared to help parents understand some of the challenges and barriers they might face in relation to parents’ technology-mediated work with their children. To help prepare them for conversations around parental challenges and barriers, PTs research and pull together a Public Service Announcement pamphlet, video tutorial, or infographic related to technology access, use/over-use, or troubleshooting program specifics.

In many of the required courses, PTs work to develop their knowledge of how to work with families, focusing on the importance of having open lines of communication, building positive relationships. PTs are asked to practice some strategies (writing letters to parents, creating newsletters) to achieve these goals once licensed practitioners. PTs also engage in applying these strategies for communicating and building relationships through technology-applied means--

communicating via email, blogs, text messages, and/or shared calendars. PTs also tinker with photo and video sharing sites and social media pages (Puerling, & Fowler, 2014).

PTs view the Explore More Learning Center (<http://exploremorelearning.bravesites.com>) and The Blue School (<http://www.blueschool.org/>) websites and social media outlets to construct knowledge about connecting and communicating with parents in a technology-rich society—to explore “school appropriate” uses. To help PTs develop competency in these forms of communication and to understand and work with policies related to privacy and children’s identities being put onto social media, PTs practice blog writing—embedding shared calendars, and images of the children’s work/explorations. They also explore strategies for safeguarding children such as taking pictures from behind to show children’s hands and their work, cropping out faces, or blurring out the children’s faces as alternative ways to still utilize the technologies, but remain within the parameters of the school’s policies.

Sharing a child’s learning and interests with their parents is a more specific/narrow form of connecting and communicating, but arguably as important as communicating the general happenings/announcements of a school day. There has been a huge shift in the assessment of young children (see, Paciga, et al., 2015)—away from more authentic forms of assessment such as observation, anecdotal notes, and work samples and toward more data driven systems of checklists and testing. Innovative technologies have the potential to shift assessment back to more developmentally appropriate practices by using authentic assessment applications that can just as easily quantify authentic assessments into hard data; we’ve worked in Evernote to manage our authentic assessments in our college-level coursework (adding tags for goals, students, and inserting audio/video/visual evidence), but there are several electronic portfolio applications currently available and more on the horizon.

T

To support PTs in this regard, faculty use some of the same tools we expect PTs to use in documenting PT progress in preservice coursework—photos, videos, and audio recordings—to provide a richer and more authentic assessment of student progress. The earlier these authentic documentation tools appear in teacher preparation programs, the more confident PTs will become with using the technology; this level of confidence is very important in implementing it into the classroom later (Ertmer & Ottenbreit-Leftwich, 2010).

Creating to Demonstrate Understanding and Problem Solving

The third example of tinkering relates to using technology to create. PTs build an incredible amount of knowledge in a technology integration course by (1) exploring something low-tech, such as an overhead projector, tape measure, flashlight; (2) thinking about possible uses for the object/tool beyond the typical and conventional; (3) using equipment that is more high-tech to record a short “how-to” video for their low-tech object; (4) using movie editing tools to package the video (faculty offer verbal scaffolds as necessary); and (5) publicizing/sharing their video (posted on the class learning management system or YouTube). This creates a situation in which the technology can be used with purpose, but with low stakes attached, fostering more risk-taking and exploring. In addition, PTs are simultaneously developing their understandings of recording, editing, and publishing video—something the PTs engage in as part of the assessment process during student teaching.

Another way PTs have constructed knowledge in this domain is through exploration of a piece of software (Book Creator or Explain Everything) to document their own learning. PTs were instructed to use iPads to document their observations about patterns and numbers in nature while on a hike (i.e., photos, videos, or voice memos with illustrations). Afterward, they took time to explore three

applications that could be used for communicating their learning to a wider audience. Each application had options to import images, add audio tracks, and/or insert text/overlay. PTs chose two of the applications to explore and then presented their observations about patterns and numbers to the larger group by using one application. PTs identified and discussed what they found challenging or intuitive about the applications and how they might overcome or harness those when using the software applications with children. The spin-off of these experiences was that several students began utilizing these applications during their student teaching experiences as a way to document the class' learning through shared writing experiences.

FUTURE RESEARCH DIRECTIONS

There is room for additional research studying the design of coaching/professional development infrastructures as related to technology integration. For example, are there ways in which teacher education programs can use different role modeling strategies and experiences to support understanding? How can mentor teachers and professional learning networks circumvent the under-prepared teacher-preparation faculty? In what ways might teacher preparation coursework facilitate a shift in the societal perceptions of teacher as “knower” toward teacher as “facilitator”? As some research already indicated, this is an institutional problem and relates to the university's ability to develop consistent strategies for ensuring technology integration by all faculty members (Lavonen, et al., 2006). More comprehensive research on how successful institutions have developed strategies to overcome these obstacles would be incredibly helpful.

Also, it is prudent to explore the impact of reflection and analysis of technology integration on PTs' utilization of technology in the content areas. Though the research shows reflection is an

important part of developing an understanding of technology integration (Goktas et al., 2009), more research in this area will help teacher education programs develop strategies for more effective reflective practice.

CONCLUSION

Technology can be a great tool for teaching and learning, but only when teachers understand it, know how to use it and can integrate it in developmentally appropriate ways. This chapter suggested several areas of development that need to be addressed by teacher preparation programs in order to support better technology integration into the early childhood classroom. We provided examples of ways that our teacher preparation programs work to construct this knowledge with preservice teachers—supporting preservice teachers’ understanding of developmentally appropriate technology practices, knowledge of authentic technology uses, and participation in hands-on technology experiences that connect knowledge or theory to practice.

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Preservice Teacher: Student pursuing a degree for initial certification/licensure in teaching field (early childhood education, elementary education).

Reggio Emilia Approach [REA]: An educational philosophy focused on early education that was founded by Loris Malaguzzi in Reggio Emilia, Italy; its fundamental principles include that (1) children are capable of their own learning; (2) children form their understandings through their interactions with others; (3) children are communicators; (4) the child's environment teaches; (5) the adult is a mentor and guide; (6) documenting children's expression of knowledge helps guide the child's learning.

Tinkering: Process by which students explore, create, and construct knowledge about the world around them.

Effectiveness of Teacher Training in Using Latest Technologies

T

Revathi Viswanathan

B. S. Abdur Rahman University, India

INTRODUCTION

Teachers who teach English as a second language (ESL) in a developing nation often feel the need for updating their knowledge of new teaching trends by attending in-service training programs or professional development courses. It is believed that such learning paves the way for providing a curriculum that integrates the use of technology within and beyond the language classroom. In this context, it must be stated that teacher training programs prove to be effective when they offer practical experience to teachers in new teaching methods. OECD (2009)'s comparative report defined effective professional development as, "on-going, includes training, practice and feedback, and provides adequate time and follow-up support. Successful programmes involve teachers in learning activities that are similar to ones they will use with their students, and encourage the development of teachers' learning communities" (p.3). Mathew (2014) defines the terms, teacher training, teacher education and teacher development. She quotes Widdowson (1983) and Richards and Nunan (1990), according to whom training, "deals with familiarising student teachers with techniques and skills to apply in the classroom" (p.29). Mathew explains teacher development as "a voluntary process, ongoing, bottom-up, since the starting point is the teachers' own experience where new information is sought, shared, reflected on, tried out, processed in terms of personal experience and finally 'owned' by the teachers" (p.29). Similarly, Evans (2002) quotes Grossman (1994, p. 58) according to whom professional development of experienced teachers could be in

the form of "workshops, study groups, Ž reside chats, a district-wide colloquium for middle school teachers, action research projects, and conversations with the professor-in-residence ...'(p.3). A professional development experience could be presented as a workshop or other formally related meetings. (Quattlebaum, 2012). In this chapter, the author would elaborately discuss the workshop, which she conducted for teachers (who represented various Indian states) and trained them in using the hand-held devices for teaching language skills. Further, she would throw light on the responses given by the participants, which reflected the effectiveness of the program.

BACKGROUND

Need for Teacher Development

Leadership and Teacher Development Branch (2005) believe that the high quality of professional learning helps teachers to improve their effectiveness in teaching. Carlson and Gadlo (n.d) consider the importance of teacher training in technical skills and say that teachers "need professional development in the pedagogical application of those skills to improve teaching and learning" (p.119). They advocate the need for providing lifelong professional preparedness to teachers through a three dimensional approach of giving pre-service training, in-service training through workshops, seminars and short courses that provide pedagogical and technical support to teachers. Teachers have to plan their teaching based on learners' needs and learning styles. They

DOI: 10.4018/978-1-5225-2255-3.ch664

need to expand their knowledge by learning the changing trends in teaching and learning processes. With the emphasis on using digital technology, it is advisable for teachers to get trained in using the latest technologies in order to provide individualized learning and instant feedback to students' performance. Sanders and McCutcheon (1986) classify teaching practices in three ways and one among them is 'structuring practices' which discusses the need for creating conditions for teaching-learning processes to take place. Training programs are nowadays conducted both online and face-to-face for educating teachers in using advanced technology and it is believed that such hands-on experience would help them to create proper learning conditions to students.

Teacher development programs have relevance to Mezirow (1997)'s theory of transformational learning. According to the theory, faculty development programs "aim at changing individuals' thoughts and actions" (Saroyan, Amundsen, & Li, 1997, p.96). Mezirow believed in the aspect that adult learners would change their practices when they change their basic assumptions about learners, role of teachers and the educational goal. Applying the transformational theory for conducting teacher training programs in using technology, it could be said that it educates teachers about the need for using the required tools for promoting students' language skills, students' level of comfort in using the devices, the way to integrate the use of tools with regular teaching and the extent to which technology would enhance their teaching style.

Saroyan, Amundsen and Li (1997) discuss the faculty development program that they designed based on Ramsden (1992)'s theories and Mezirow's transformational theory. It was a product-oriented program and focused on enabling participants to design a course and demonstrate skill and exhibit self-confidence in teaching it. In the micro-teaching session, they were asked to select and use the strategies which would foster learning among students. They were encouraged to give a self critique besides getting the feedback from peers. They were asked to give their inputs

in the beginning and after the program so that their change of perception towards teaching could be evaluated. The data collected was related to the instructional formats that were developed on the basis of Ramsden's and Mezirow's theories. It was evident from the analysis of the feedback given by the participants and teachers that they had changed their view of teaching as knowledge transmission to more focused activity of attaining learning outcomes.

Considering the need for educating teachers in using mobile technology, it is worthwhile to mention that Montrieux, Vanderlinde, Schellens and De Marez (2015) conducted a qualitative focus group study for reviewing the impact of tablet devices towards teaching and learning practices. They used Vanderlinde and Braak (2010)'s e-capacity model for framing a few research questions while conducting the semi-structured interview with a select few teachers and students. According to the e-capacity model, teachers need to have the competence for handling technology and showing teacher development. The interview was conducted after the teachers and students made use of tablet devices for six months. The analysis of the responses given by teachers and students revealed that the introduction of innovative technology helps teachers to integrate technology with traditional teaching. It was found that the "innovative teachers" had adopted the role of coach and had changed their teaching style in order to mobilise students' learning processes.

Similarly, Lynch (2015) presents the outcome of the two studies which revealed that school students (35% of them according to the study) were more interested in doing teachers' lessons or activities by using their tablet.

Maduakolam & Bell (2003) discuss the product-based faculty professional development model that was designed in order to train teachers to use and integrate advanced technologies into instruction and infuse technology into all teacher education courses. In the workshops that were conducted, the participants were given hands-on experience of creating instructional resources and

develop web sites using Microsoft Front Page and Dreamweaver. It was believed that such experience would create opportunity for the participants to provide the required resources to students. The participants were asked to use Microsoft Outlook to collaborate and communicate with other faculty members. The outcome of two years of training through workshops and implementation proved that the teaching and learning became very exciting and the faculty efficacy in technology usage and integration was very encouraging besides the networking done among faculty members.

It must be stated that the current workshop too could be related to the above-mentioned theory as it focused on changing tertiary level teachers' misconception of using mobile devices for teaching and educating them about new teaching technique to enhance students' language skills.

METHODOLOGY

Participants

The two-day workshop was conducted for teachers at the collegiate level and about 26 teachers representing various South-western states of India participated in it. These teachers were enrolled based on their primary interest in using ICT in the classroom and their willingness to use mobile phones in the teaching and learning process. They were asked to bring either a Smartphone or a Tablet or an iPad for getting hands-on experience in using them during the workshop.

The technical support was provided by the department of Computer Applications in B.S. Abdur Rahman University, where the workshop was organised. To explain, the wireless network facility (with two additional access points) was given in the seminar hall, which was used for conducting sessions on using mobile phones for accessing resources and applications. Similarly, the Internet connectivity in the language lab was also enhanced for the participants to access the free container

applications in the desktop for creating individual mobile apps for teaching and learning process.

T

Teacher Training Design

The aim of conducting a two-day workshop on Mobile Enhanced Language Learning (MELL) was to promote the concept of mobile learning, which is otherwise called as, M-Learning, among college teachers for teaching the language skills. It was believed that the training offered would develop teachers' teaching skills for facilitating learning even beyond the classroom. Carlson & Gadio (n.d) mention that, "teacher professional development in the use of technology should embody and model the forms of pedagogy that teachers can use in their classrooms" (p.121). They go onto specify the need for empowering teachers and including activities that develop their knowledge and skills, encourage them to use a variety of learning strategies, develop higher order thinking skills and demonstrate how technology facilitates teaching skills, to list a few. Crompton (2015) refers to the International Society for Technology in Education (ISTE), which specifies standards for coaches. It states that one of the ways by which technology coach could determine the professional development need of staff is, "design, develop and implement technology-rich professional learning programs that model principles of adult learning and promote digital age best practices in teaching, learning and assessment" (n.d). As stated in transformative theory, professional development programs should bring a few changes in teachers' teaching techniques. Villegas-Reimers (2003) believes that professional development programs that deal with, "activities that include both technical and conceptual aspects of instruction" (p.19) would prove to be most effective in sustaining change in teachers (Baker and Smith, 1999). To achieve this objective in this workshop, the tertiary level teachers were given hands-on experience in using the mobile phones in the three aspects such as 1. Using the mobile phone for browsing online

resources and activities, 2. Accessing mobile applications relating to language skills, and 3. Creating an app for handling language tasks. The purpose of focusing on this ubiquitous technology was to facilitate learning anywhere and everywhere. It is believed as Bjerede, Atkins & Dede (n.d) mention that “Student engagement in school will increase, as will educational outcomes, because the wireless devices build on strengths and preferences youth have developed by using these tools outside of classroom settings” (p.5).

The first aspect focused on encouraging teachers to search for useful language games and activities in their mobile phones and relate them to the learning modules. The resources included text, audio and video files that could be shared with students and encouraged to learn from those files. The second aspect focused on creating awareness of various language learning apps readily available in Google play store that could be installed in the mobile phones. For example, Google play store offers free language learning applications such as ‘Learn English’, ‘Speak English Daily’, ‘Real Business English’ to name a few, which provide learning content to students. Similarly, the play store also presents a few language teaching tools such as, ‘VoiceThread’, ‘ipadio’ and a few more that offer scope for training students in a particular language skill. ‘VoiceThread’ is a cloud application, which requires an updated version of Adobe Flash. A new user has to create a VoiceThread account with a username and password by accessing the web site www.voicethread.com. The user who wants to use the mobile app could register by accessing the app in the mobile and navigate to the account tab. He has to click on ‘join VoiceThread’ button and fill in the short registration form. The user can complete his registration by accessing the email and retrieving the verification message to confirm his account. This tool helps a user to create presentations, upload, share and discuss different types of media, which includes presentations, images, audio files and videos, and also comment on the slides created by a user. Similarly, ipadio is another application (available in android and

iOS versions) that allows its users to make phone calls and also share through social audio and video platforms. The user has to create an account for using the app. The recorded audio (in MP3, WAV and many more formats) and videos could also be broadcasted with the help of this application. It was felt that the exposure to such applications would help teachers to work on two things like prepare worksheets relating to the content present in the app and integrate mobile learning as part of teaching technique. The final aspect of the workshop that focused on creating an app was to enhance the ICT skills in language teachers and prepare them for sharing teaching content through the ubiquitous tool, mobile phone. As mentioned earlier, the current workshop was conducted with the consideration of above-mentioned aspects and the hands-on experience was provided by two teacher trainers, the author herself and a freelance consultant, Dr.P.N.Ramani.

Training

On the first day of the workshop, the participants were given a questionnaire and were asked to identify the scope of using technology (Appendix) based on their practical usage. The purpose was to make them self-assess their level of comfort in using a smart phone over a desktop. The questionnaire had five questions and the first question dealt with the extent to which the participants use a Smartphone. It had more than 30 options and the participants had to mark unlimited number of options based on their utility. The second question, which was close ended type, reviewed their preference in using a mobile phone over a desktop computer. The third question (an open-ended question) expected participants to list out the similarities between a desktop computer and a mobile phone. For the fourth question, the participants had to specify the multi-media features in a mobile phone and for the fifth question, they were asked to specify the infrastructural facilities required for using a mobile phone in a teaching and learning process. The answers given were

Figure 1. Screenshot of participants' involvement in a workshop session

discussed during the session and the participants were asked to retain the questionnaire for reassessing their perception of using Smartphones, after attending all the sessions. As a continuation to this discussion, an initial orientation on Mobile teaching and learning was given with the following objectives:

1. To create awareness of the advantages of using mobile technology.
2. To show the possibility of offering blended learning through the use of mobile devices.
3. To make participants realize the possibility of providing flipped learning through mobile devices.

4. To educate the teacher participants in technical know-how of providing an infrastructure for offering mobile learning to students.

The interaction along with the presentation provided lot of insights into the challenges faced by teachers in their institutions. While a few pointed out about the facilities available within the language classrooms, a few others shared their lack of knowledge of installing apps and the rest of the participants were apprehensive in using the mobile devices within the classroom. It was decided to address the challenges during the course of the workshop. After the introductory session, the participants were introduced to

Figure 2. Screenshot of participants' involvement in a workshop session

the resources that could be accessed online in the mobile devices. The participants worked in pairs and accessed those resources in their devices. The content was shared with others. They were also asked to focus on how the resources could be made use of while training students in language skills. Teachers shared a few language tasks that integrate the use of the resources accessed in the mobile phones.

In the next session, the resource persons provided input on the language application tools that are readily available in Google play store and iOS store. The features of those tools were discussed and the participants were asked to download and install in their mobile devices. They had to work in groups, explore the method of using the tools, and design one or two tasks pertaining to LSRW skills. Each group was assigned a skill and they had to work on it. It must be admitted that the participants worked with lot of enthusiasm and came out with two to three skill-based tasks. The groups shared their tasks with other group members too. The groups had to again work on the tasks to carry out suggestions given by other members. The participants were asked to keep the tasks safe so that they could be uploaded in the app, which would be created on the next day.

On the second day of the workshop, the participants were exposed to the designing of a free app using two different container apps, YAPP and Appypie. YAPP (which was available as a free container app until the early months of this year) was founded by Seidman and Melia in 2012. It could be downloaded in iOS and Android devices. The latter app, Appypie, is a paid container app and could be accessed in Windows phones or iPhones. It is worthwhile to mention that these container applications offer the facility to share the teaching and learning content through various pages created by a teacher. The objectives of using the applications were

- To enhance teachers' knowledge of ICT skills and progress to the next step of creating a teaching and learning environment in a mobile device.

- To show them the possibility of designing a mobile application without using html language.
- To demonstrate and provide hands-on experience to upload learning material in app.
- To show them the way to broadcast to the users about the material or task uploaded.

The session was conducted in the language lab that has high-speed Internet connectivity and the author demonstrated the way to create an app, create pages like Newsfeed, Simple text, upload Videos, provide links to Audio files and broadcast about the tasks uploaded in the pages. The participants created an app by logging into the websites, www.yapp.us and www.appiepie.com. They posted their images in the home page of the app, gave a name to their app, created a page for schedule, an invitation page for enrolling users and a simple text page.

As mentioned earlier, they uploaded the tasks prepared on the previous day in the simple text page created by them.

When the session continued in the seminar hall, the participants could broadcast the tasks and pages that they uploaded to the trainers and other participants through their app. This proved to be a very interesting and exciting experience to the participants.

Discussion

Harwell (2003) mentions that the content of a professional development program should “generate and contribute new knowledge to the profession and increase the ability to monitor students' work, in order to provide constructive feedback to students and appropriately redirect teaching”(p.4). She goes on to stress the effectiveness of a professional development program, which gives opportunity to teachers to learn new classroom practices. Considering the outcome of the workshop, it must be stated that the current workshop had achieved the objective of exposing

Figure 3. Screenshot of mobile applications created by participants

Figure 4. Screenshot of the worksheet uploaded in an app

Figure 5. Screenshot of the video task uploaded by a participant

teachers to a new technology and that was evident in their enthusiasm to integrate multimedia with the teaching tasks and upload them in the simple text page. A few even downloaded YouTube videos pertaining to a particular task created by them for facilitating listening skill and uploaded them in the simple text page.

In addition to the various tasks uploaded by the participants, the feedback given by the teacher participants about the workshop showed the extent to which the workshop proved to be an effective teacher development program. The responses could be categorized under knowledge enhancement and application. With regard to knowledge enhancement, the participants felt that the workshop served as an eye opener to the world of mobile technology. They found the sessions to be comprehensive and the content gave them exposure to M-learning. The participants specified that the third session (that dealt with creating an app) was very useful as they could successfully create an app for their students and even attempt uploading tasks in the simple text page. With regard to application of the knowledge gained, they felt confident that they would be able to implement the new technique of using mobile for teaching and learning in their classrooms. Apart from these responses, the participants had generally stated that

the sessions were very interactive, resourceful, motivating, and informative and created curiosity to know more about m-learning.

SOLUTIONS AND RECOMMENDATIONS

It is worthwhile to mention that the participants showed lot of commitment to participate in every session of the workshop. After the practical sessions, the final session was devoted for interacting with the participants relating to the challenges they faced in every session. One of the challenges was the low connectivity to a few mobile phones of participants. Moreover, the battery in their mobile phones could not hold the charge for long due to access of application and had to be charged now and then. Another apprehension that the participants stated was the possibility of keeping track of students' access to the application, which would be created by the concerned teacher, periodically. It was suggested that teachers could include an evaluation component for the activities uploaded in the mobile application to monitor completion of tasks given and that would ensure students' periodic access to application. Considering the need for using technology for teaching and learning process, teachers of English can augment the use of mobile devices by utilizing the existing applications and offer blended learning experience to students along with classroom learning. It would prepare them for lifelong learning and train them in the aspect of self-direction. By preparing skill-based worksheets teachers would enhance their skill of material production and that would pave way for professional development. As Montrieux et al (2015) mention, "Introducing new technology into education generates a simultaneous need for professionalization" (p.15). Further, as Vanderlinde and van Braak (2010) suggest in their e-capacity framework, educators have to follow an educational policy that provides techni-

cal and pedagogical support in order to facilitate the development of new teaching and learning practices (Montrieux et al, 2015). In other words, the concerned institutions have to offer adequate technical support (i.e enhancing wireless connectivity within the campus) for teachers to pursue the above-mentioned endeavour.

FUTURE RESEARCH DIRECTIONS

Considering the growing interest of teachers in using mobile phones for augmenting learning, it is suggested that teacher researchers can do research on using the devices for implementing the concept of Flipped learning to teach any particular language skill or language skills in general. Similarly, teachers can work on interdisciplinary research for creating a common Learning Management System (LMS) for providing teaching components to students. In other words, teachers of English and a core subject teacher (either from Information Technology or Computer Science department) can work together to create a mobile app for the utility of teachers and students. It is worthwhile to mention that this kind of research projects would draw even alumni (who belong to one of the above-mentioned departments) of an institution, who is in the field of application development, to play an active role to design an application for his teachers. It further paves the way for an institute and industry collaboration through a project work.

CONCLUSION

Thus, it must be stated that the workshop had largely covered the method of using mobile devices for teaching and learning purposes. Needless to say, these teacher training programs create more opportunities for teachers to explore new teaching techniques.

KEY TERMS AND DEFINITIONS

Advanced Technology: Technology that reflects the latest trends.

Flipped Learning: A new pedagogical approach that promotes collaborative learning among students. According to the approach students are expected to gather information relating to a topic, from the resources provided by the teacher and work as a team to discuss the content in the classroom.

Free Container Application: An application that provides lot of features, which could be used by the users for free to suit their requirements.

In-Service Training: Training that is offered to teachers while they are in service to enhance their teaching skills.

Learning Management System (LMS): It refers to the platform created either virtually or physically for promoting teaching and learning process. Teachers use it for sharing information to teach a concept and also for training students in a particular skill.

Mobile Enhanced Language Learning: The support provided by handheld devices for promoting language learning.

Needs Assessment: A questionnaire which is used for finding out the needs of the teachers or learners or educators in order to offer training accordingly.

Transformational Learning: A learning experience that has a greater impact on an individual and brings a change in one's behaviour and teaching technique.

T

APPENDIX: SCOPE FOR USING TECHNOLOGY

Answer the following questions and tick the appropriate options given below:

1. What do you do with your Smart phone?
 - a. Check facts
 - b. Take photos
 - c. Make videos
 - d. Carry out tests
 - e. Read the news
 - f. Dictionary
 - g. Calendar
 - h. Write down ideas
 - i. Listen to music
 - j. Images
 - k. Stopwatch/timer
 - l. Read eBooks
 - m. Voice Recorder
 - n. Discover related subject material
 - o. Document scanner
 - p. Calculator
 - q. Edit videos
 - r. Publish in the class blog
 - s. Track blog visits
 - t. Make presentations
 - u. Remote control
 - v. Communicate
 - w. Updates
 - x. Locate points on the map
 - y. Tweet
 - z. Assess Students
 - i. Share Notes
 - ii. Digital Whiteboard
 - iii. Weather
 - iv. Measure Productivity
 - v. Play
2. Why do you prefer a mobile phone to a desk top computer?
 - a. Easy to carry
 - b. Easy to type out information
 - c. Communicate without delay
 - d. Receive user-friendly commands
 - e. Have more options for sharing information
3. What similarities can you find between a desktop computer and a mobile phone?
4. Can you specify the multi-media features offered by a mobile phone?
5. What infrastructural facilities would you prefer for using mobile phones in the teaching and learning process?

Role of Educational Leaders in Supporting Beginning Teachers in Al Ain Schools in the UAE

T

Salam Omar Ali

Brighton Collage Al Ain, UAE

INTRODUCTION

Principal support of new teachers has been cited as one of the primary factors that influences both general and special education teachers' retention in the profession. However, principal leadership is a critical component of creating environments that support new teachers to meet the complex and diverse needs of their students (Correa & Wagner, 2011). Principals should work on having an effective school-based induction activities to provide all novice teachers with the induction they need.

Novice teachers may face some obstacles which might cause stress, anxiety and lack of self-assurance (Saenz-Lopez, Almagro, & Ibanez, 2011). Therefore, schools should implement an individual structured program to support the beginning.

A principal's role in the induction of novice teachers is multifaceted. Findings from several research studies, such as Andrews, Gilbert, & Martin, 2006; Correa & Wagner, 2011) suggest that building administrators who are effective in supporting novice teachers promotes a positive school climate, serves as an instructional leaders, and actively supports induction and mentoring programs.

BACKGROUND OF THE STUDY

A beginning teacher is a person who has been hired to work in a new environment with people he/she does not know. The new appointed teacher goes through a period of transition from being a

student to into becoming a teacher. In such a case, beginning teachers need supervision and support to adjust to their new roles. Moreover, being exposed to new policies, and untried materials, gives the new teachers the feeling of being lost. It is no wonder that some of the new teachers leave their jobs simply because they are left to "sink or swim" and of course many sink and leave to feel better. However, this paper highlights the importance of the principal's role in supporting novice teachers in Al-Ain in the UAE.

Research Questions

This paper answers the following questions:

1. What are the present practices of principals in Al-Ain schools in supporting their beginning teachers?
2. How can the educational leaders develop these practices to have the best induction program for their beginning teachers?
3. What needs would the new appointed teachers in Al-Ain district, have and what would they expect from an effective school-based induction program?

LITERATURE REVIEW

Around 50% of teachers who remain in education field leave their profession after five years (Evans, 2008). On the other hand, different reports indicate that 25%-50% of beginning teachers resign during their first three years of teaching

DOI: 10.4018/978-1-5225-2255-3.ch665

(Voke, 2002; NCES, 1999). Other studies showed that it is within the first five years of teaching; approximately half of the teachers will leave the occupation (Ingersoll & Smith, 2003; Murnane et. al, 1991). Novice teachers usually face many difficulties in the profession. In a study for Veenman (1984) the perceived problems of beginning teachers were classified into eight kinds of problems; they are 1) classroom discipline, 2) student motivation, 3) dealing with individual differences, 4) assessment of student work, 5) relationships with parents, 6) organization of class work, 7) inadequate instructional resources, and 8) dealing with problems of individual students. Moreover, Corbell (2008), stated that there are ten factors affect the beginning teachers' perceptions of success, such as, Mentor Support, Colleague Support, Administration Support, Classroom Management, Student Success, Instructional Resources, Assignment and Workload, Parental Contacts, Satisfaction, and Commitment. However, teachers' success can be ensured by providing them with a comprehensive, coherent professional development program (Wong, 2004).

Nothing is more important for student learning than the quality of the classroom teacher. Effective teachers manage to produce better achievement regardless of which curriculum materials, pedagogical approach, or reading program is selected (Allington, 2003). Teacher turnover usually leads to lower student achievement, and of course low student achievement leads to teacher turnover. Indeed, teaching has been characterized as an occupation with high levels of attrition or high early career turnover, especially among beginners (Darling-Hammond, 2003). Furthermore, some studies showed that most of the teachers who decided not to continue working in this career were much affected by the lack of knowledge about the school system, classroom management, dealing with the parents and many other different issues that they could not handle. As a result, it is of great importance to know that induction programs of the beginning teachers have an effective impact on their

decision whether to continue teaching or to stop it. Wong stated that, what keep a good teacher are structured, sustained, intensive professional development programs. However, these programs allow new teachers to observe others, to be observed by others, and to be part of networks or study groups where all teachers share together, grow together, and learn to respect each other's work (2003). Any induction program should be evaluated to check its effectiveness in meeting the needs of the new teachers. The increased focus on induction programs as an agent of reform in education has resulted in a great deal of research. Most studies, however, are outcome-based, generally used to ensure the financial support needed to continue induction programs in particular areas (Abell, Dillon, Hopkins, McInerney, & O'Brien, 1995). Induction is seen as the crucial phase of teacher development, which links Initial Teacher Training and in-service education for established teachers (Commonwealth Department of Education, Science and Training, 2002, p 11). Prior to any program establishment, principals should bear in mind teachers' needs before shaping or applying any induction program.

To sum up, referring to the fact that education sector plays an important role in shaping the whole society, it is very crucial to pay attention to the main element in the educational process; the teachers who are the most important factor in maintaining high quality education (Barber & Mourshed, 2007). Gless and Moil (2005) argue that nothing is more important for student learning than the quality of the teacher. Supporting teachers and providing appropriate induction program improves their teaching practices (Breux & Wong, 2003). Induction programs save the time of teachers in discovering the right instructional practices on their own. Literature suggests that effective school-based induction programs should include the following:

- Individual structured induction program (Huling-Austin, 1992). That means to find out the real needs of each teacher.

- Reduced workloads for the new qualified teachers (NQTs) and mentors for observation and assistance (Bleach, 1999 and Commonwealth Department of Education, Science and Training, 2002); opportunities to observe other experienced colleagues in order to explore good teaching and learning practice and opportunities of being observed by other trusted colleagues followed by discussion and feedback (Bleach, 1999; Huling-Austin, 1992 and Ingersoll and Kralik, 2004).
- Ongoing professional development relevant to the needs of NQTs (Commonwealth Department of Education, Science and Training, 2002; and Ingersoll and Kralik, 2004).

METHODOLOGY

A mixed method of quantitative and qualitative methods is adopted to conduct this study.

Sample and Instrumentation

A total of 20 principals and 30 of their new appointed teachers were chosen from public and private schools in Al Ain school district to administer a questionnaire and participate in interviews.

Opportunity sampling was used through a process of randomization. A convenience sample is made up by people who are easy to be part of the study, such as this one.

The study instruments include (1) a 12-item Likert scale, questionnaire with 4 response choices, strongly agree, agree, do not agree, and strongly do not agree, and (2) a semi structured interview

to gather information on principals' and teachers' perceptions and interactions between principals and newly appointed teachers regarding first year experiences at school and induction practices.

Teacher Questionnaire (See Appendix)

Demographic information was collected, including gender, years of experience and whether a mentor has been provided within the school.

The questionnaire then included 25 items; each assessed using a 4 point scale, running from Strongly Agree to Strongly Disagree.

Principal components factor analysis using oblimin rotation was used to look for common factors within the 25 items. Three factors emerged accounting for 52% of the variance ($p < 0.005$). Scales were constructed on the basis of this.

Scale 1: Mentor Support

This scale consists of items 2-6 on the questionnaire. Reliability analysis was used to check for internal reliability. A Chronbach's alpha of $r = 0.75$ was obtained. As such, the items were combined generating a "Mentor Support" scale.

Scale 2: Instructional Resources

This scale consists of items 16-21 on the questionnaire. Reliability analysis was used to check for internal reliability. A Chronbach's alpha of $r = 0.76$ was obtained. As such, the items were combined, generating an "Instructional Resources" scale.

Scale 3: Assignment and Workload

This scale consists of items 22-25 on the questionnaire. Reliability analysis was used to check for internal reliability. A Chronbach's alpha of $r = 0.66$ was obtained. Item 22 was deleted, resulting in a Chronbach's alpha of $r = 0.79$. As such, items 23-25 were combined, generating an "Assignment and Workload" scale. Items 7 to 15 did not load onto

Table 1. Breakdown of sample according to gender and group

Group	Male	Female
Teacher	15	16
Principal	11	9

any of the 3 main factors. As such, these items were not included in any further analysis.

Principal Questionnaire (See Appendix)

Demographic information was requested, including gender, and years of experience. There were then 12 items on the questionnaire, consisting of statements to be answered on a 4 point Likert scales running from strongly disagree to strongly agree.

Principal components factor analysis with oblimin rotation revealed 2 factors in the 12 questions, accounting for 55.30% of the total variance ($p < 0.001$).

Scale 1: Support

According to the factor analysis, items 2, 4, 5, 7, 8, 9, 10, 11, 12, which accounted for 40.25% of the total variance were combined. Reliability analysis for this scale revealed a Chronbach's alpha of $r = 0.86$. These items were used to construct the scale "Support".

Scale 2: Direction

Items 2, 3 and 6 were combined to construct the scale "Direction". The Chronbach's alpha for this scale was $r = 0.61$.

Questionnaire items and interview questions are designed to collect information to answer main questions of the study with use of previous literature review and surveys. They were designed to the UAE context to better inform the case study of Al Ain school district.

DATA ANALYSIS AND FINDINGS

This section presented the results of analysis of the questionnaires, for both principals and teachers, and the interviews, as follows.

Teacher Questionnaire Results

Demographics

Only 7 from the 32 respondents indicated the number of years they had been teaching. Of those 7, the number of years teaching ranged from 3 to 20, with a mean of 10.86 ($SD = 7.54$)

From the 32 respondents, 23 did not give an indication as to whether they had a mentor. Of the 9 who did complete this item, 6 did not have a mentor.

Due to the small number of respondents giving demographic information, demographics, with the exception of gender, were excluded from any further analysis.

Mentor Support, Assignment and Workload, and Instructional Resources Scales

Table 2 shows the means and standard deviations relating to these scales. No differences according to gender were obtained on any of the scales. Table 1 shows the means of the three scales.

T-tests were used to look for differences between the three scales. Significant differences were found between all 3 scales: Mentor Support, Assignment & Workload ($t = 2.28$, (31), $p < 0.05$), Mentor Support and Instructional Resources

Table 2. Mean scores and standard deviations of the three teacher scales

	Mentor Support	Assignment and Workload	Instructional Resources
Mean	13.63	14.87	6.81
SD	2.94	2.96	1.73

($t=12.09$, (31), $p<0.001$), and Assignment & Workload and Instructional Resources ($t=15.04$, (31), $p<0.001$).

The t-tests indicate that respondents felt least positive about Instructional Resources, more positive about Mentor Support and mostly positive about Assignment & Workload. These results seemed similar to what the literature review indicates.

Principal Questionnaire Results

Of the 20 participants, only 9 gave information as to the number of years teaching. Of those, the number of years taught ranged from 11 to 30, with a mean of 19.78 ($SD=7.82$). This indicated that most of the participating principals had many years of teaching before assuming the management positions in their schools.

Due to the small number of respondents giving demographic information, demographics, with the exception of gender, were excluded from any further analysis.

Support and Direction Scales

Table 3 shows the means and standard deviations relating to the Support and Direction scales. No differences according to gender were obtained on any of the scales. Table 2 shows the means of the two scales. A higher mean for support (28.15 vs. 9.25) than direction is shown to indicate that teachers in this study viewed the support needed highly than given directions. Newly appointed teachers have the tendency to feel that they are ready and well prepared graduating from their programs to teach, hence, need of less direction, but greater support.

Table 3. Mean scores and standard deviations of the two principal scales

	Direction	Support
Mean	9.25	28.15
SD	1.74	4.20

T-tests revealed a significant difference between the two scales ($t=21.49$, (19), $p<0.001$). This indicates that principals felt more positive about the level of support they give rather than the amount of direction they give.

Inter-Relationships Between Principal and Teacher Questionnaire

Pearson's correlational analysis found only one relationship between the five scales. The findings showed a positive correlation between 'Mentor' and 'Instructional Resources' ($r=0.45$, $p<0.01$). This indicated that the more positive the teacher felt about their mentoring, the more positive they felt about instructional resources. No relationships were found between how well principals felt they were directing and supporting and the teacher's opinions.

The Interview Results

It is obvious from the findings of the interviews questions (see pages 22&23) that the principals showed that they provide a lot of care to the novice teachers in terms of supporting them, giving them a reasonable workload and providing them with adequate time to plan and meet the other teachers in the same field. On the other hand, teachers kept on complaining about their current situation as their real needs have been never met. According to the interviews, most of the principals said that they are a great help to their novice teachers, but they are restricted by the time; they do not have enough time to guide and assist the new appointed teachers. Some of the principals stated that: there is a big need to appoint a mentor for all new novice teachers to enable them to produce high quality of teaching and to give them the self-confidence they need to continue their career. Others said that they would like to help and support their novice teachers personally, but the principals' duties are too complicated as they should make sure that everything at the school is just on the right track, simply they find their jobs very exhausting and

stressful. Regarding the relationship between the principals and the novice teachers, most of them commented that they are very keen to have a very good relationship with their novice teachers, through which novice teachers can express their ideas and talk about their needs freely without being afraid of the possibility of being fired. This idea is supported by the literature (Brock and Grady, 1998)

FUTURE RESEARCH DIRECTIONS

Although this study explored the role of the principals in supporting novice teachers, at the same time, it gave us ideas for future research, such as to investigate the impact of school climate on novice teachers' retention and the effect of having mentors in supporting novice teachers' motivation.

SOLUTIONS AND RECOMMENDATIONS

There is a big gap between what the novice teachers expect to get from their principals and what they are getting. Therefore, principals have to integrate an induction program into the school system and to become as part of the school's culture.

Depending on the results, in order for the beginning teachers to accept their profession, they need to be provided them with support and guidance. An induction should be taken into the stake holders' consideration to help teachers develop their abilities and skills through an ongoing professional development. The new appointed teachers who will be under that program should have less workload than any other teacher to make sure that they will not be overwhelmed with work. Furthermore, Schools should make it possible for the novice teachers to have enough time to meet the other professional experienced teachers who could provide them with help and assistance regarding

planning and other educational issues. Principals have to be very keen to let their novice teachers meet the experts coming from outside the school. Special courses should be attended according to the teachers' experiences. Furthermore, the following should be taken into consideration:

Mentoring

It is basic need for novice teachers. Principals should make sure that new appointed teachers get mentors as mentoring helps them feel that there is someone cares about them and helps them deal with day-to-day worries.

Peer Coaching

This is one of the most important needs of novice teachers. Many educators across the globe use various coaching models to improve the performance of teachers and raise the attainment of their students. Coaching is about helping people to learn.

Principals and the school management team should be the models of sharing good practice through the distribution of leadership, giving the head of faculties (department) the anatomy to shape their departments. Additionally, they should have their input into the school strategic planning and professional development of all staff.

CONCLUSION

Novice teachers are obviously in need of support to overcome the obstacles they may face. Consequently, it is the role of the principals to understand the stress that novice teachers have and to help them reduce their sufferings. Moreover, the quality of the relationship between the novice teachers and their principals is so important.

Principals have to offer support for their novice teachers in the proper atmosphere through different ways, such as providing them with opportunities

of orientation sessions to understand the school policy. Experienced teachers can also provide basic teaching tips to inexperienced teachers; ideas that can be immediately implemented into the classroom with new ideas in teaching methodologies.

Induction programs that are designed for novice teachers should meet their diverse needs; these needs can be classified into the following:

- **Psychological Needs:** To prepare the novice teacher to endure any psychological issue and to manage stress is an important need.
- **Professional Needs:** Informing teachers about the importance of professional development for their career, their duties, different ways of dealing with students and with the other teachers, legal issues and any other important professional needs that should be met before and during the service.
- **Instructional Needs:** To prepare the new appointed teachers for their classrooms instruction is very important. Principals should make sure that novice teachers are ready to use different instructional methods, techniques and resources.
- **Social Needs:** Providing teachers with opportunities to start having good relations with parents and colleagues using different ways such as, open days for teachers and staff, social activities for teachers, and above all, participating in extracurricular activities.

Finally one should realize the importance of supporting novice teachers, providing them with the right training they need and connecting them with knowledgeable, caring and experienced teachers to help them build up their confidence, efficacy and success in serving diverse students with diverse needs.

KEY TERMS AND DEFINITIONS

T

Mentor: A facilitator who usually helps new appointed teachers find their ways in the profession.

Novice Teachers: Teachers who are new to the profession of teaching.

Peer Coaching: When two or more colleagues (teachers) work together to share good practices and help each other build new teaching skills.

APPENDIX

Teacher's Questionnaire

The Role of Principals in Supporting the New Teachers (Teacher Version)

Full Name (optional): -----

Your school's name (optional): -----

Years of experience as principal: -----

Years of experience as teacher (if any): -----

Gender: _____

Do you have a mentor assigned to you by the school or another experienced teacher to provide you with assistance?

_____ Yes

_____ No

Use the following scale to answer each of the questions.

1: strongly disagree

2: disagree

3: agree

4: strongly agree.

Table 4. Mentor support (teacher questionnaire)

#		1	2	3	4
1	The mentoring relationship is or would be important to me.				
2	My mentor or an exemplary teacher has provided assistance with classroom management.				
3	My mentor or an exemplary teacher has provided assistance with instructional concerns.				
4	My mentor or an exemplary teacher encourages me to reflect about my teaching.				
5	Working with my mentor has been a positive experience.				
Colleague Support					
6	I have opportunities for meaningful conversations with other novice teachers in a setting free of evaluation.				
7	I have common planning times with other teachers at my same grade level or subject area.				
8	I have opportunities to visit and observe exemplary teachers.				
9	I have a colleague in my same subject area (secondary) or grade level (elementary) who will answer my questions.				

continued on following page

Table 4. Continued

T

#		1	2	3	4
Administration Support					
10	The administration at my school provides appropriate feedback for my discipline's decisions				
11	The administration at my school encourages me to be an effective teacher.				
12	The administration has oriented me to the school and staff.				
13	I am satisfied with the contact I have with my administration.				
14	The administration provides me with effective instructional leadership.				
Instructional Resources					
15	I have been provided with curriculum that aligns with the Ministry's objectives for my grade level or subject area.				
16	I have the curriculum materials I need to teach effectively.				
17	I feel confident in my ability to use the instructional technology available to me.				
18	The school provides professional development that is valuable to my instruction in the classroom.				
19	I feel confident in my ability to grade student work.				
20	I feel comfortable with reporting the assessment of my students' work.				
Assignment and Workload					
21	I think the number of preparations I have for my classes is appropriate for a beginning teacher.				
22	I have at least one period per day that I can devote without interruption to planning for my classes.				
23	My overall teaching workload is reasonable.				
24	Beginning teachers are allowed to choose whether to take on extra duties or not.				

The Principal Questionnaire

The Role of Principals in Supporting New Teachers

Full Name (optional): -----

Your school's name (optional): -----

Years of experience: -----

Gender: _____

Use the following scale to respond to each questionnaire item by checking the appropriate response box as follows

1: strongly disagree

2: disagree

3: agree

4: strongly agree.

Table 5. Mentor support (principal questionnaire)

#		1	2	3	4
1	I direct new teachers to perform at acceptable level at school				
2	I work with new teachers so they can blend in school culture				
3	I make sure to that new teaches are oriented and made aware of Ministry policies				
4	I am fully satisfied and pleased from the help and support given to the newly appointed teachers				
5	I think about my professional conduct in light of moral and ethical standards.				
6	I allow new teachers to meaningfully converse with other novice teachers in a setting free of evaluation.				
7	We provide new teachers with induction on all aspects of school				
8	I assist new teachers to transform skills to meet teaching and learning needs				
9	I evaluate new teachers more often to give feedback to them				
10	I attend to new teachers' school problems and issues				
11	I believe that new teachers can benefit from assign them mentors				
12	I assign mentors or veteran teacher to guide new teachers				

Do you have any additional comments?

Thank you for your cooperation.

Principal's Interview Questions

- To which extent are you satisfied with the help and support you provide the novice teachers with?
- What kind of obstacles you face in helping and supporting novice teachers?
- Do you think novice teachers need a mentoring program? Justify your answer.
- If you feel that your school is fair with novice teachers regarding the workload and the support they get explain how?

Teacher's Interview Questions

- To which extent are you satisfied with the help and support you get from the principal?
- What kind of obstacles you face in your career as a novice teacher?
- Regarding training and support, do you think novice teachers are getting what they need?
- If you feel that your school is fair with novice teachers regarding the workload and the support they get explain how?

The Technological Pedagogical Content Knowledge of EFL Teachers (EFL TPACK)

T

Mehrak Rahimi

Shakiba Pourshahbaz

Shahid Rajaei Teacher Training University, Iran

INTRODUCTION

ICT-integrated teaching is not as easy as it might seem and it requires compound skills and knowledge base for both teachers and learners. The theoretical framework of the knowledge teachers need to teach with technology has been referred to in the literature by the term TPACK or Technological and Pedagogical Content Knowledge. TPACK is a complex framework that explains teacher knowledge for technology integration and its intertwining concepts.

This heavy demand of teaching professional career is rooted in a string of developments and advancements in technological arena that started in mid-20th century and has been flourishing in this century swiftly. It is not far-fetched to say that every aspect of peoples' lives is changing along with advances of technology in the 21st century. Computers, cell phones, televisions, and other technological devices are no longer considered new inventions, as they are now being used daily by everyone. Education like other fields of science must not fall behind this trend. The curriculum, methodologies of teaching, resources and materials, teachers, students and the school environment need to adapt and change to match the requirements of the modern world in which technology plays an undeniably significant role.

For some people, staying current with technology in the field of education is a more important issue as they look at the progress of ICT (Information and Communications Technology) to be a

solution to many pedagogical problems (Pedersen, 2001). This implies a prevalent force in the modern world to embrace technology more than ever. In the field of education, this is translated into smart schools that are equipped with innovative technological facilities such as interactive whiteboards, developed computer laboratories and a variety of software programs.

Many researchers have investigated the effects of ICT on enhancing teaching and learning in different ways. It is believed that ICT can have positive effects on education such as learning efficiency, learning effectiveness, access, convenience, motivation, and institutional efficiency (Hubbard, 2009). With that being said, ICT integration in education is expected to lead to better learning which automatically demands more qualified teaching conditions.

In this era, educational administrators push educators to empower themselves professionally in line with the trend of technological normalization. Hence, many teachers face the dilemma of 'changing' themselves with the new teaching condition. With this pushed change in the educational system, of course come some unintended consequences for the teachers, some of which are actually not so desirable (Pedersen, 2001). Some of these consequences are already evident: ICT integration can take a huge load off teachers if the required resources and skill are present; however, it is also likely that it reduces the teaching quality in environments that lack the needed resources and/or teachers do not possess enough technology

knowledge. As a matter of fact, research suggests that one of the most important personal factors that hinder technology normalization is the lack of ICT knowledge (Mahdi, 2013). Studies in this regard reveal that in order to benefit from all aspects of technology in education, ICT should be integrated in the educational system in a way that it is used by teachers and students every day, as an integral part of the lesson, just like pen and pencil (Bax, 2002). Naturally, this requires much knowledge of technological affordances from both sides.

According to what was presented above, it is obvious that the lack of knowledge to use technology creates a huge burden for teachers to integrate technology in the process of teaching (Yurdakul, et al., 2012). Teaching is known to be one of the most stressful occupations ever since teachers are believed to suffer from different social and political discriminations leading many of them to feel frustrated (Warrad, 2013). Now in the 21st century, the force of technological empowerment and ICT integration in schools has multiplied the stressful nature of the profession for teachers. TPACK or ICT-literacy can be the answer to teachers' prayers regarding successful ICT integration in schools. To make the whole process of education more successful and to protect the well-being of teachers, empowering teachers to handle their job appropriately is a very crucial issue. TPACK is the knowledge of most value in today's world and understanding this complex knowledge is the very first step in the path of successful ICT integration into the process of teaching. With that being said, this chapter aims at investigating the concept of TPACK in terms of education in general and language teaching in particular.

BACKGROUND

Considering the complexity of teaching profession in general, it is not a surprising thing to claim that the knowledge required by teachers to integrate ICT into their teaching is also complex in nature. The idea of creating a construct for explaining this

knowledge goes back to 1986 in the Shulman's description of pedagogical knowledge (PK). In his seminal work, Shulman suggested three categories of content knowledge required to handle the teaching of a specific subject matter: subject matter content knowledge, pedagogical content knowledge, and curricular content knowledge. By the advancement of technology, however, the attention to teachers' knowledge base was naturally drawn to technological arena and the way it is interwoven with other types of content knowledge. Research on TPACK can generally be divided into three main categories (Yurdakul et al. 2012):

1. Definition and measurement of TPACK,
2. Effects of professional development on TPACK, and
3. Evolution of the TPACK.

In the first phase of TPACK research, the studies tried to systematically define TPACK (e.g., Koehler, Mishra, Yahya, and Yadav, 2004) and create a deep understanding of the complex interrelationships between content, pedagogy and technology knowledge and the contexts in which they occur (Yurdakul et al. 2012).

The second phase of TPACK mostly focused on investigating the role of TPACK in the professional development of pre-service and in-service teachers (Koehler & Mishra, 2005). Most studies in this phase were experimental and tried to explore whether teachers' professional development programs can actually influence their TPACK level. Not surprisingly, it was found by most of these studies that teachers' professional development has a positive influence on developing teachers' level of TPACK (e.g., Doering, Veletsianos, Scharber, & Miller, 2009; Graham et al., 2009).

Following this phase, research on TPACK construct shifted to focus on developing an integrated model of TPACK considering its various dimensions separately and in relation to one another. However, the number of studies with a focus on TPACK as a unified and consistent body

is very limited (Archambault & Crippen, 2009). It might be safe to say that the study that has been carried out in 2012 by Yurdakul and associates has been successful in developing a consistent and comprehensive framework. This study includes technology integration in classrooms based on different competencies and components in teaching-learning process. As a result, this framework has been chosen to define TPACK and extend its components into teaching English as foreign language (EFL) teacher knowledge base in the current study.

The Definition of TPACK

The fact that teaching is a highly complicated and demanding profession is accepted by most educators. Teachers are constantly expected to apply many domains of complex knowledge structures across different contexts (Mishra, Spiro

& Feltovich, 1996; Spiro & Jehng, 1990). With that being said, integrating technology into the teaching process is not a simple task. The skills needed to use ICT effectively should consider various aspects including subject matter, knowledge of student thinking and learning, and most importantly, knowledge of technology (Putnam & Borko, 2004).

TPACK is defined in literature as a complex framework to explain teacher knowledge for technology integration. Teacher knowledge in this definition is not simply the ability to use technology; it is a complex interaction of three layers of knowledge within the TPACK framework: technology, pedagogy and content (Yurdakul et al, 2012). In a more concise definition, TPACK is defined as “an understanding that emerges from interactions among content, pedagogy, and technology knowledge” (Koehler & Mishra, 2009, p.66). In order to understand and define TPACK

Figure 1. the TPACK framework and its three components
Source: Koehler & Mishra, 2008, p. 12.

in a more comprehensive way, however, it is required to understand the underlying themes and core concepts of TPACK framework.

Figure 1 is one of the early conceptualizations of TPACK construct displaying its core intertwining concepts: Technological Knowledge (TK), Pedagogical Knowledge (PK) and Content Knowledge (CK). Technological Knowledge (TK) refers to one's ability to use and integrate technology into everyday activities and also the ability to recognize the situations which technology can help to enhance or impede reaching a goal. Pedagogical Knowledge (PK) is defined as teachers' deep knowledge about different teaching and learning methodologies, approaches and practices such as planning lessons and classroom management techniques. Content Knowledge (CK) is teachers' knowledge of the specific subject matter that is going to be taught or learned including theories, approaches, ideas, concepts and frameworks (Koehler & Mishra, 2009).

According to this definition, there are other components in TPACK framework which are created as a result of the interaction among the three

domains of teacher knowledge. These components include: TCK (Technological Content Knowledge), PCK (Pedagogical Content Knowledge), TPK (Technological Pedagogical Knowledge), and TPACK (Technological Pedagogical Content Knowledge) (Koehler & Mishra, 2009; Yurdakul et al, 2012). Table 1 contains a short summary of the definitions and examples for each of these seven dimensions synthesized from literature review (Cox & Graham, 2009; Koehler & Mishra, 2009; Mishra & Koehler, 2006 as cited in Chai, Koh & Tsai, 2013, p.33).

Despite the fact that TPACK is the basis of technological knowledge framework, early conceptualizations of TPACK framework focused on seven distinct components of technology knowledge (TK, PK, CK, TPK, TCK, PCK and TPACK) (Shahin, 2011; Shmidt et al, 2009). The lack of attention to the main component TPACK as a whole led to the development of a more comprehensive framework of TPACK considering all these separate parts along with a main core.

Table 1. Definitions and examples of TPACK dimensions

TPACK Constructs	Definition	Example
TK	Knowledge about how to use ICT hardware and software and associated peripherals	Knowledge about how to use Web 2.0 tools (e.g., Wiki, Blogs, Facebook)
PK	Knowledge about the students' learning, instructional methods, different educational theories, and learning assessment to teach a subject matter without references towards content	Knowledge about how to use problem- based learning (PBL) in teaching
CK	Knowledge of the subject matter without consideration about teaching the subject matter	Knowledge about Science or Mathematics subjects
PCK	Knowledge of representing content knowledge and adopting pedagogical strategies to make the specific content/topic more understandable for the learners	Knowledge of using analogies to teach electricity (Shulman, 1986)
TPK	Knowledge of the existence and specifications of various technologies to enable teaching approaches without reference towards subject matter	The notion of Web quest, KBC, using ICT as cognitive tools, computer-supported collaborative learning
TCK	Knowledge about how to use technology to represent/ research and create the content in different ways without consideration about teaching	Knowledge about online dictionary, SPSS, subject specific ICT tools e.g. Geometer's Sketchpad, topic specific simulation
TPACK	Knowledge of using various technologies to teach and/ represent and /facilitate knowledge creation of specific subject content	Knowledge about how to use Wiki as an communication tool to enhance collaborative learning in social science

Source: Chai, Koh & Tsai, 2013, p.33.

The Conceptual Model of TPACK

TPACK is not a simple framework and this is due to the complicated nature of teaching profession. Knowing about technology and how to use it in everyday activities is just one part of the story; knowing how to integrate this knowledge into instruction by using proper pedagogical skills and classroom management abilities is a quite different paradigm. This matter has been seen within a new framework of TPACK where the original concepts are preserved and the concepts and components are interwoven more comprehensively. The framework (Figure 2) consists of four main components: design, exertion, ethics and proficiency (Yurdakul et al, 2012).

- **Design:** It refers to teacher's ability to create and develop curriculum plans, and combining proper technological tools and resources to enhance the teaching and learning situation.
- **Exertion:** It refers to the ability to implement the design plans in the teaching and learning situation and also using appropriate technologies to assess and evaluate students learning.

Figure 2. The framework and factors of TPACK-deep scale

Source: Yurdakul et al, 2012, p. 973.

- **Ethics:** It focuses on the ability to consider copy right issues and show ethical behavior as a professional in online educational environments and also when using technological tools and resources.
- **Proficiency:** It refers to teachers' leadership ability to integrate technology into the teaching process in the most effective way.

THE EFL TPACK

Teaching English as a foreign language takes place when language learners learn English in a nonnative English speaking country. In this situation, English is usually taught by nonnative teachers who are not expected to be as fluent and accurate as native English speakers as they themselves have been EFL learners. Due to the lack of exposure to real and authentic language input in the EFL environments, EFL teaching strongly depends on technology especially in teaching listening and speaking (Liu et al., 2014). Technological tools have made EFL teaching effectively possible as early as 1960s and thus knowing how to use technology has always been an undeniably important aspect of EFL teachers' professional development (Yang, 2000).

In order to help EFL teachers become successful in their profession, there is a need to define the conceptual model of EFL TPACK. Earlier, the knowledge/competency base of EFL teacher education programs has been proposed to be based on a tripartite model including (Rahimi, 2008, p. 4):

- **Content Knowledge (CK):** Knowledge of the subject matter, English language.
- **Pedagogical Knowledge (PK):** Knowledge of science of teaching and pedagogy, knowledge of generic teaching strategies, beliefs, and practices; along with support knowledge, the knowledge of the various disciplines that would enrich teachers' approach to the teaching and learning of English.

- Pedagogical Content Knowledge (PCK):** Knowledge/competency of teaching in reality, the specialized knowledge of how to represent content knowledge in the classroom and how students come to understand the subject matter in the context of real teaching; the students' problems and ways to overcome those problems by considering all variables related to their learning (teaching materials, assessment procedures, parents, etc.).

Combining this model with the TPACK model presented earlier, the EFL TPACK can be specified more meticulously for EFL profession. The components of EFL TPACK are presented in Table 2.

By going through the EFL TPACK model presented above, it is clear that when ICT use is accompanied by appropriate knowledge base on teachers' side, it can help EFL teachers to enhance all aspects of their teaching; from materials development to classroom management to appropriately diagnose language learners' learning problems and

Table 2. The EFL TPACK components

EFL TPACK Constructs	Definition	Example
CK	Knowledge of the subject matter without consideration about teaching the subject matter	English language proficiency
PK	Knowledge about the students' learning, instructional methods, different educational theories, and learning assessment to teach a subject matter without references towards content	knowledge of generic teaching strategies, beliefs, and practices along with support knowledge, the knowledge of the various disciplines that would enrich teachers' approach to the teaching and learning of English (e.g. educational psychology, second language acquisition), such as knowledge of using metacognitive strategies to enhance learning
PCK	Knowledge of representing content knowledge and adopting pedagogical strategies to make the specific content/topic more understandable for the learners	the specialized knowledge of language teaching and learning; how to represent English as a foreign language in the classroom and how language learners come to understand English in the context of real teaching; discovering the students' problems and ways to overcome those problems by considering all variables related to their language learning (teaching materials, assessment procedures, parents, etc.), such as knowledge of conducting group activities to improve students' learning
TK	Knowledge about how to use ICT hardware and software and associated peripherals	IT literacy, knowledge of technology in general, knowing about basic computer software (web browsers, media players) and devices (printers, scanners, digital cameras)
TPK	Knowledge of the existence and specifications of various technologies to enable teaching approaches without reference towards subject matter	IT integration literacy, the ability to use technologies to teach and interact with students
TCK	Knowledge about how to use technology to represent/research and create the content in different ways without consideration about teaching	Knowledge of CALL teaching/learning: CALL materials development and lesson planning
TPACK	Knowledge of using various technologies to teach, represent, and facilitate knowledge creation of specific subject content	Knowledge of CALL teaching/learning: using multimedia software/games as a tool to enrich teaching language macro skills (listening, speaking, reading, writing) and components (grammar, vocabulary, pronunciation); class management and assessing students' learning; presenting content via appropriate language teaching strategies by using proper technological tools intermingled with appropriate language teaching methodology/instructional materials

solving those problems professionally. In this way, ICT integration would be a truly wise choice for every EFL classroom paving the way of creating a more authentic and native-like language teaching and learning environment for both EFL teachers and learners.

Assessing EFL-TPACK

Research suggests that integrating ICT into education has become significantly important for European and Western countries in the last decade (Elmaifi, 2014). In the same vein, the expansion of technological infrastructures has made ICT one of the most important issues addressed in educational systems of developing countries. One reason is to prepare the labor force of a world in which technology is being normalized. As a result, the mainstream education needs technologically literate teachers to handle classes of digital natives and direct them in the right path of using technology for their academic and professional goals. Having said this fact, teacher professional development is now considered a highly important resource in the field of language teaching to help EFL teachers develop their knowledge base to catch up the needs of today's modern world (Avalos, 2011; Kleinsasser, 2013). Professional development programs in the area of CALL (Computer Assisted Language Learning) are one example (Hong, 2010).

All around the world, short term pre-service and in-service courses have been prevalent ways enabling educators to develop their professional capacities. Needless to say, these programs cannot be very fruitful without a comprehensive needs analysis. A wise step to do so would be investigating the needs of EFL teachers regarding ICT literacy. It would be useful to gain comprehensive insights about EFL teachers' current level of TPACK, and find out accurate facts about their strong and weak points considering different dimensions of TPACK knowledge base. In this way, the program would be certainly more effective and lots of time, money and resources would be saved.

A number of instruments have been developed to assess TPACK. The differences of these instruments lie in different TPACK frameworks that have been developed to this date. The TPACK survey developed and validated by Schmidt et al. (2009) is a widely used instrument to assess TPACK. This scale assesses TPACK in terms of the seven distinct components of TPACK: TK, CK, PK, TCK, PCK, TPK and TPACK. The 24 item TPACK survey developed by Archambault and Crippen (2009) is another example. The survey, like the previous one, examines TPACK by the seven components of TPACK based on the prototypical model. What these two instruments have in common is that they have been built on the commonly used TPACK framework (Koehler & Mishra, 2008; Mishra & Koehler, 2006). The TPACK scale developed and validated by Yurdakul et al., (2012) however is a little different from these two. The scale has been built on the TPACK framework developed by Yurdakul et al., (2012) and consists of four sub-scales including Design (10 items), Exertion (12 items), Ethics (6 items), and Proficiency (5 items).

Two instruments have been specifically developed to measure language teachers' TPACK. The first one is an EFL-TPACK questionnaire that investigates EFL students' perceptions of their teachers' TPACK (Tseng, 2014). In the process of developing the scale, the TPACK prototypical model with seven components was put into test (TK, CK, PK, PCK, TCK, TPK, and TPACK). The result showed that EFL teachers' TPACK consists of five factors, three of which were found to be TK, TPK, and PCK and two of which were the combination of PK and CK; and TCK and TPACK respectively.

In a very recent work, Baserab, Kopchac, and Ozdend (2016) developed and validated a self-assessment survey that examines TPACK of EFL teachers. The TPACK-EFL survey, as it is called by the authors, aims to provide an assessment tool for pre-service foreign language teachers and addresses subject-specific pedagogies and technologies. The result of data analysis revealed

a seven-factor structure for TPACK including TK, CK, PK, PCK, TCK, TPK, and TPACK.

What is vitally important to mention here is that both scales showed that EFL TPACK has the same factor structure as the general scale, verifying the seven-component model of TPACK (Shahin, 2011; Shmidt et al, 2009). However, what distinguishes these scales from the original version is the way items are loaded on the extracted factors. This means that the general model as a whole is valid to be used across subject matters; however, context specific studies are required to explain the details of the construct TPACK.

SOLUTIONS AND RECOMMENDATIONS

In today's digital world, EFL teachers face an immediate need to 'technologize' their pedagogical knowledge, meaning that they need to integrate ICT literacy with their professional knowledge (Liu et al., 2014). The arrival of the Internet and wireless technologies can be considered a huge driving force that guides EFL teachers in the path of ICT integration. With learners being exposed to unbounded Internet resources wherever they are at any time, EFL teachers have no choice but to embrace technology as an integral part of their teaching. Failure to do so will certainly create a situation in which teachers are not able to function effectively in their job (Mishra, Koehler & Kereluik, 2009).

Considering the modern world's need which is global communication, one of the most effective EFL teaching methods is considered to be communicative language teaching (Bygate, 2001). ICT integration can certainly provide opportunities to bring various authentic materials and activities that can provide a suitable near-native language learning atmosphere. Using technology can also be an appropriate solution to big class size dilemma that most EFL teachers deal with (Liu

et al, 2014). With the presence of high TPACK, EFL teachers can assess their students' learning more accurately by using technology to make more room for learners' individual differences. Keeping these issues in mind, it is obvious that EFL teaching cannot effectively move towards the communication goal without using technology alongside the required TPACK. As a result, the role of EFL TPACK in successful technology integration is obviously significant.

FUTURE RESEARCH DIRECTIONS

Living in the era of communication, TPACK has now become a global phenomenon that interests many researchers around the world. Different researchers investigated TPACK in various ways, from developing a sound theoretical framework for TPACK to assessing teachers' TPACK level in different countries.

However, research on TPACK is far from over. Further research is urged to investigate EFL teachers' TPACK considering their individual differences, attitudes, age and working experience. Experimental research can also be done on manipulating certain variables to measure their effects on improving teachers' TPACK level. It is also recommended to do qualitative studies to triangulate the data and corroborate the findings with the literature.

CONCLUSION

In this era, technology has a huge impact on every aspect of people's lives, from their careers and socializing to education and entertainment. In an attempt to keep up with other fields, educational administrators and teachers need to welcome technology as an inseparable part of the curriculum. Teachers are the key agents of education with the professional responsibility of preparing the new

generation and thus they should be able to use ICT in their classrooms effectively. According to a longstanding body of research, this task is simply not possible without the required knowledge and skills to use technology. Understanding the TPACK framework is the primitive step for all educators in the path of developing their TPACK level. This demands that the educators of different disciplines and specialties become familiar with their field-specific TPACK. To enrich EFL teacher education paradigm, this chapter reviewed and presented the available models/frameworks of TPACK and then proposed the EFL TPACK and how to assess it based on the available literature.

KEY TERMS AND DEFINITIONS

CALL: Computer-assisted language learning, the search for and study of applications of the computer in language teaching and learning.

CK: Content Knowledge, knowledge of concepts, theories, conceptual frameworks.

Digital Natives: A person born or brought up during the age of digital technology and so familiar with computers and the Internet from an early age.

EFL: English as a foreign language: the study of English by nonnative speakers living in a non-English-speaking environment.

ICT Literacy: The ability to use digital technology, communication tools, and/or networks.

PK: Pedagogical Knowledge, generic knowledge about how students learn, teaching approaches, methods of assessment and knowledge of different theories about learning.

TK: Technological Knowledge, an understanding of the way that technologies are used in a specific content domain.

TPACK: A framework to understand and describe the kinds of knowledge needed by a teacher for effective pedagogical practice in a technology enhanced learning environment.

Ubiquitous Teachers' Training and Lessons Learned with the *uProf!* Model

INTRODUCTION

The current landscape of open and smart learning challenges calls for disruptive educational policies and systems (Li, Chang, Kravcik, Popescu, Huang, Kinshuk & Chen, 2015; Middleton, 2015). All stakeholders (i.e., policy makers, educational institutions, teachers, learners, parents) have renewed roles and degrees of participation in the learning process. Undeniably, though, teachers are on the frontline. On the one hand they are required to absorb their shifting function into facilitators in technology-enhanced learning environments, and on the other hand they are pressured to become more aware lifelong learners.

This technological uptake and consistent change and innovation have been urged by the decisively faster pace that economic systems, social relations and individuals have had since the diffused embracing of Web 2.0, that is the web of social networking tools (Leone & Guazzaroni, 2010), towards Web 3.0, that is a more connected, open and intelligent network thanks to semantic applications (Spivack, 2013).

Definitely, living, working and learning are smarter and smarter, that is they seamlessly accommodate next generation technology (i.e., smartphones, tablets, tablet PCs, sensor network nodes, contact-less smart cards, RFID and QR codes), socialised (Leone & Biancofiore, 2015), and ubiquitous, that is wireless and characterised by high mobility and embeddedness (El-Bishouty, Ogata, & Yano, 2007; Leone & Leo, 2011a). Most

European countries have made significant investments over the last years with a view to ensuring universal access to information and communication technologies (ICT), with considerable success (Education, Audiovisual and Culture Executive Agency, 2011). Specifically, embedding ICT in education and training systems has required relevant changes across the technological, organisational, teaching and learning environments of classrooms, workplaces, and informal learning settings; further efforts, though, are required in this direction (European Commission, 2008; Education, Audiovisual and Culture Executive Agency, 2011). A precondition for using computers in educational contexts is that they are widely available and users are familiar with them. With reference to formal education, data (Education, Audiovisual and Culture Executive Agency, 2011) show that currently no great disparity between schools in availability of ICT equipment exist, but a lack of educational software and support staff still affect instruction. Thus, the solution to an effective use of ICT in education and training is not technology itself, but an advancement in understanding how smart technologies are and can be used to support learning, and what are the barriers in the way of success.

Being an ICT-integrating teacher means going beyond ICT skills, and developing an understanding of the complex relationships between pedagogy, content and ICT (Alayyar, Fisser & Voogt, 2012). Moreover, while in most European countries centrally promoted online resources and

general pedagogical support are available to guide teachers' practical implementation of innovative technology-enhanced learning in the classroom (according to TIMSS - *Trends in International Mathematics and Science Study 2007*) (Education, Audiovisual and Culture Executive Agency, 2011), no research literature seems to document the activation of tailored in-class techno-pedagogical tutoring to teachers during the implementation. A later study carried out on behalf of the European Commission (Pelgrum, 2010) shows that teachers often have difficulties in implementing ICT in the teaching-learning process and that they need support to accomplish this task. Finally, the outcomes of more recent research experiences (Leone, 2013) highlight that teachers perceive in-class techno-pedagogical tutoring as a basic need for the enhancement of their professional skills and, as a result, of their students' learning.

This article illustrates features and outcomes of the experiences with *uProf!*, a model for teachers' professional training in ubiquitous learning by tablets and Quick Response (QR) codes. The model was designed, implemented and successfully validated in 2012 within a full-immersion, learner-centred and metacognitive course for 80 Italian high school teachers who are part of a school network for the enhancement of curriculum continuity from middle into high school. Later on, *uProf!* has been used to provide continuous professional training and tailored in-class tutoring during these teachers' first implementations of technology-enhanced learning experiences.

BACKGROUND

Ubiquitous devices allow to create a Computer Supported Ubiquitous Learning (CSUL) environment. A CSUL could be embedded in everyday life (Ogata & Yano, 2004) and is characterised by permanency, accessibility, immediacy, interactivity, situatedness and adaptability (Curtis, Luchini, Bobrowsky, Quintana, & Soloway, 2002; Leone & Leo, 2011a). Learning theories for CSUL are authentic learning (Brown, Collins & Duguid,

1989), situated learning (Lave, & Wenger, 1991) and learning by doing (Schank, 1995).

These premises highlight the strong potential that ubiquitous learning (uLearning) provides to a lifelong learner, that is to the activator of economical, cultural and social growth of our society and of the systems within. In a lifelong learning vision, the individual is a primary resource of knowledge: the individual's empowerment extends progressively to his/her context and to society as in a network. Empowerment has to be considered as the success key of the relation between a community of practice and the organization to which it is linked. The "double link" described by Wenger & McDermott & Snyder (2002) is crucial for the survival and the development of both, community of practice and organization: the first conducts the improvement of its members' expertise through informal interaction and learning; the second relies on experts grown in the community of practice to identify and implement strategies, to focus on objectives and outcomes of its units.

Through this process old and new borders of knowledge, competence and skills merge and widen. Coherently, traditional educational systems need to evolve into more open and flexible systems, systems that could allow users to choose a learning path according to their learning styles, needs and interests, at any time along their life. In a lifelong learning vision, change and learning are strictly linked: change requires learning and, vice versa, no learning takes place without change (Leone, 2010).

As a result of the current evolution of education systems, the aims of vocationally-based education are beyond training and instruction, to encompass the development of standard features essential to professional competence and lifelong learning (Savery & Duffy, 1994). These include the acquisition of domain knowledge and competencies, and of generally applicable competencies (i.e., ability to adapt to change and participate in change, communicate, collaborate in groups, and be self-directed lifelong learners) (Minasian-Batmanian, Koppi & Pearson, 2000).

THE *uProf!* MODEL

In the label of this model, *uProf!*, “u” stands for “ubiquitous” and “Prof” for “a professional”, that is, “a person engaged in an activity and having an impressive competence in it”, for “professional”, that is characterized by or conforming to the technical or ethical standards of a profession”, and for “professor”, that is either a teacher and “a person who affirms a faith in something” (in the definitions from the Merriam-Webster dictionary), the belief in ubiquitous learning.

The *uProf!* model has been devised for teachers’ professional training in ubiquitous learning, in order to support them in acquiring the mind-set (beyond the skill-set) to successfully facilitate technology-enhanced learning. The *uProf!* model has been developed in the vision of lifelong learning and thus of the individuals’ empowerment, that is the teachers’ and subsequently their students’ empowerment, by learner-centred environments characterised by a bottom-up approach, personalisation and adoption of new technologies as means of re-mediation of networked knowledge (Leone & Guazzaroni, 2010).

Needs, Objectives, and Competences

The *uProf!* model aims to meet teachers’ need for knowledge and skills to implement effectively inclusive ubiquitous learning environments, and for in-classroom tailored tutoring during initial implementations.

General learning objectives of the *uProf!* model are: supporting the acquisition and improvement of techno-pedagogical knowledge, competences and skills that teachers could spend in their different domains; providing teachers with tools to personalise and making flexible their students’ learning.

Specific learning objectives are: increasing teachers’ awareness of the relevance of digital skills for the development of active citizenship; enriching the teachers’ professional and personal

background by knowledge exchange practices, on the basis of innovative teaching-learning experiences with ICT; allowing the acquisition of innovative teaching methodologies for the promotion of key competences, with a focus on the *QRcode* format as a framework that supports uLearning (Leone & Leo, 2011b; Leone, 2012; Leone, 2014).

The *uProf!* model can develop higher cognitive, digital and professional competences as follows: by increasing learners’ awareness of the relevance of digital skills for the development of active citizenship; by selecting the most suitable innovative teaching-learning methodologies, on the background of lifelong learning, in relation to the context, aiming at empowerment, inclusion and personalised learning; by using the innovative teaching-learning methodologies and materials acquired; by implementing the *QRcode* format.

Paradigm and Learning Strategies

The *uProf!* model draws on socio-constructivism (Vygotsky, 1986; Varisco, 2002) and andragogy (Knowles, 1970). It foresees the adoption of brainstorming, problem solving, learning by doing, collaborative and cooperative learning, game based learning, simulations in presence and in immersive virtual environments, and metacognition. The model can be an effective inclusive learning tool since it facilitates personalised and flexible learning if a learner-centred approach is adopted, an approach attentive to each learner’s diverse needs (UNESCO, 2009).

Organization: Learning Environments, Tools, and Human Resources

The physical places to implement the *uProf!* model are the classroom with a wireless connection or a hot spot, where learners operate, individually or in a group, on paper-based and digital learning material, by the various ubiquitous devices available, and any other place by ubiquitous devices with an Internet connection. The learn-

T

ing environment is, therefore, both physical (i.e., the classroom and the learners) and virtual (i.e., web-based, with interactive activities in and out of a distributed community of practice - Wenger, McDermott & Snyder, 2002). Various systems (e.g., Learning Management Systems) and tools can be used to implement the *uProf!* model, according to the learners' personal and professional needs, priorities and learning styles. Specifically, personalised learning is provided by the use of ubiquitous devices (anytime, anywhere learning), by the adoption of adaptive mechanisms (e.g., *conditional activities* in Moodle) which operate upon the assessment of learners' learning styles and prior and progressively acquired knowledge, and by the use of multimodal learning materials (Leone, 2013).

The length of the implementation can vary in relation to the number and the extension of the uLearning modules of the designed path.

Necessary human resources are: one or more (teachers') trainers, that define strategies, objectives, contents and activities; a learning technologist, who has extensive knowledge, management and troubleshooting expertise of all the educational technologies that could support learning and teaching within the path; an ICT technician, that installs/checks the QR code decoder software in the mobile devices in use, checks the Internet connection and deals with general hardware and software troubleshooting.

The implementation of the *uProf!* model in a distributed learning environment requires an Internet connection and laptops, smartphones, tablets or tablet PCs, together with the use of sensor network nodes, contact-less smart cards, RFID (Radio Frequency Identification) and QR codes.

Evaluation and Assessment

The *uProf!* model is monitored at the beginning and at the end of its implementation, in order to evaluate its effectiveness and rating from the participants' point of view (evaluation), and to assess the achievement of learning objectives

(assessment). For the evaluation, the data are collected (1) by entry and exit anonymous surveys, to record teachers' digital skills, previous technology-enhanced teaching-learning experiences, motivation and expectations on the model (entry survey), and feedback (exit survey). Assessment is entirely based on self- and peer- assessment; it is carried out by close and semi-structured tests (entry test on prior knowledge and competences), direct observation (ongoing assessment) and project works and role-plays (summative test at the end of the learning path). Assessment parameters are: effectiveness of the teaching/learning methodology adopted in the project works and cohesion with the learning scenario; competence in the use of the teaching/learning methodology adopted in the project works.

Recommendations for an Optimal Implementation

The *uProf!* model is very flexible for both the trainer-facilitator and the learners (i.e., teachers), and it can be adapted to all contexts and used for all knowledge domains. Anyhow, essential elements for the success of the experience are: (1) thorough organisation and management of the necessary hardware and software; (2) an adequate familiarization of the learners with the learning environment (technology, tools and learning approach); (3) a light e-moderation by the facilitator, in order to provide a modulation of self-regulated and shared learning on the basis of the learners' silent and/or expressed requests, with the aim of supporting participants' high motivation.

uPROF! IN COMUNITA' DI PRATICA PROGETTO EUREKA

The *uProf!* model was validated within a full-immersion, learner-centred and metacognitive course for 80 Italian high school teachers, within the *Eureka* project (2012-2014), a network of 11 schools in Apulia, Italy, for the enhancement

of curriculum continuity from middle into high school.

The *QRcode* format (Leone & Leo, 2011b; Leone, 2012; Leone, 2014) was selected as element of techno-pedagogical innovation through the *Eureka* project, and for this reason played a central role in the development of the model. One of the authors of this article was the coordinator of the techno-pedagogical innovation of the project and both were the trainers.

The initial teachers' training for the *Eureka* project was delivered in October-November 2012 in two in-presence 4-hour workshops; participants worked in 16 groups of 5 and in few plenary sessions, and they used tablets and laptops. In addition, a distributed community of practice (Wenger, McDermott & Snyder, 2002) was activated, the *Comunità di Pratica Progetto Eureka*, in the eLearning space www.elearnigplace.it/corsi (Moodle) that the trainers own and manage. A large number of the tools available in Moodle were used: its adaptive mechanism of *conditional activities* to provide trainees with personalised and scaffolded learning; a learners' forum for brainstorming and problem solving, plenary discussions, knowledge exchange and sharing of best practices; group forums for collaborative and cooperative group works; tags for knowledge co-construction and sharing; assignments for individual or group works to be handed in for feedback; questionnaires and grade book for self-assessment; logs for self-monitoring learners' involvement; instant messaging for personal communications. In addition, Google Docs, for the co-production of final project works, and SurveyMonkey, for the completion of entry and exit surveys, were integrated in Moodle.

Besides being the trainees' environment for the metacognitive experience of their collaborative and cooperative learning in presence and in eLearning, the *Comunità di Pratica Progetto Eureka* was proposed as virtual environment for the realisation of the aims of the *Eureka* project itself, that is to create a network among the 11

school partners and enhance curriculum continuity from middle into high school. Hence, the *Comunità di Pratica Progetto Eureka* offered enormous potential to teachers (and, subsequently, to their students and to the institutions of which they are part), provided that the members of this community engaged in a constructive interaction for the construction and sharing of best practices.

A one-week phase of scaffolded familiarisation with the learning environment and materials was held in *Comunità di Pratica Progetto Eureka* before the workshops.

As a whole, in order to better meet institutional time constraints and trainees' learning needs, these first training sessions were made as much flexible and personalised as possible, relying on participants' and partner schools' active participation. The entire training aimed to (1) support the acquisition and improvement of techno-pedagogical knowledge, competences and skills that trainees could spend in their different disciplines; (2) provide trainees with tools to personalise and make flexible their students' learning.

Contents were focused on digital skills as necessary crosscurricular competences to be citizens of the 21st century and on the *QRcode* format (what it is and how to use it – research experiences and case studies carried out, and group *role-plays* of its implementation in an interdisciplinary scenario). The learning path included the development of innovative technology-enhanced teaching-learning methodologies (brainstorming, problem solving, learning by doing, metacognition, collaborative and cooperative learning, peer tutoring, project work). In-depth contents on inherent definitions, concepts and approaches were provided in this first phase, to subsequently facilitate the implementation of possible (interdisciplinary and not) scenarios (single learning modules or entire projects) directly in the classroom by tailored tutoring for each trainee.

Indeed, in the following months 4 of the 11 schools of the *Eureka* project network started interdisciplinary projects with the *QRcode* for-

mat. In all, 23 teachers were engaged, and they were supported by in-class tutoring on the *uProf!* model. In detail:

- In April-May 2013 (4 weeks, 9 hours a week for each class) an interdisciplinary path was developed on Italian, music, history, geography, French and maths with 4 3rd-year classes of a middle school together with 4 1st-year classes of a high school, 193 students and 14 teachers in all.
- In January-February 2014 (4 weeks, 9 hours a week for each class) an interdisciplinary path on citizenship education, geography, Italian, the arts and music with 4 3rd-year classes of a middle school together with 4 1st-year classes of high school, 187 students and 9 teachers in all.

Outcomes

The final feedback surveys pointed out that time constraints were one of the critical elements of the training sessions, but all the causes (limited budget, delays in institutional communication within the project network, missed deadlines in carrying out familiarisation and group activities) were independent from the *uProf!* model, that, instead, was successfully validated by the trainees' satisfaction and learning outcomes.

In detail, participants perceived both experiences of initial training and of in-class tutoring during the implementations of the interdisciplinary paths with the *QRcode* format as new, interesting and useful (100%) (especially for the hands-on and reusable activities and contents), flexible (94.8%), but tiring as well (57.9%) because of poor Internet connection (36.8%), time constraints (48.2%) and consequent difficulty in getting oriented with learning materials and environments (26.3%).

The respondents pointed out that learning with ICT showed the following disadvantages: it required familiarisation with technology-enhanced learning (mindset) (84.2%) and a high degree of technological know-how (57.9%); viceversa,

learning with ICT offered the following advantages: independence from time and space (94.8%), personalised learning (100%) and flexible contents (94.8%).

At the end of this experience, 52.6% of the participants affirmed that they were gratified for having learned to do new things, 21.1% were gratified for having learned new things, and the rest were frustrated because they had not been able to exploit it at the best (21.1%), deceived because it had not met their learning needs (10.5%) and happy because it was over, at last (5.3%). Finally, 78.9% would have been happy to repeat this experience in order to keep learning, to improve as a teacher, to enhance their collaborative and cooperative work skills, and to be part of a learning network.

Finally, the global perception of the experiences was positive because they represent a first opening to what learning has already become in everyday life thanks to the affordances of ICT. Nevertheless, evidence shows the need for more flexible education systems by the development of the culture of knowledge exchange, cooperative work, sense of belonging to a community as signal of growth of the system as a whole and the individual as its activator. This implies necessarily endeavours to bring oneself into question and, thus, to accept the relativism of one's professional eco system; a re-allocation of school funds is vital as well to tutor teachers directly in the classroom during the implementation of various technology-enhanced learning formats.

FUTURE RESEARCH DIRECTIONS

In the near future, the *uProf!* model will be implemented further and extensively in different grades of instruction to provide continuous professional training to teachers.

Accordingly, future research issues will be the analysis of the impact of the model on the teachers' empowerment and on their institutions, the validation of teachers' informal learning during the application of the *uProf!* model, and the ef-

fects of the use of the *uProf!* model on students' achievement of crosscurricular skills.

Further, the model could be included in a research experience in the field of business management to observe its effects and to identify margins of improvement.

CONCLUSION

Technological uptake and consistent change and innovation in education have been urged by the decisively faster pace of the knowledge society since the emergence of Web 2.0, towards Web 3.0.

Undeniably, living, working and learning are more and more ubiquitous. Embedding ICT in education and training systems has required relevant changes across the technological, organisational, teaching and learning environments of classrooms, workplaces, and informal learning settings; further efforts, though, are required in this direction. Teachers today are expected to be able to apply a wide range of digital technologies in the classroom, but they need practical support. In-class tailored techno-pedagogical tutoring is a basic need for the enhancement of their professional skills and, as a result, of their students' learning. In this regard, the *uProf!* model of teachers' professional training in ubiquitous learning by tablets and QR codes was designed, implemented and successfully validated within a full-immersion, learner-centred and metacognitive course for 80 Italian high school teachers who were part of a school network for the enhancement of curriculum continuity from middle into high school. Later on, the model was adopted to provide in-class tutoring to the teachers engaged in technology enhanced interdisciplinary implementations.

The global perception of the experience was positive. Nevertheless, margins of improvement have emerged in the participants' digital skills, in their approach to teaching and learning, in their approach to the adoption of ICT in the curriculum as a chance of holistic change and growth towards smart inclusive education.

KEY TERMS AND DEFINITIONS

Adult Education: All forms of non-vocational adult learning, whether of a formal, non-formal or informal nature.

CSUL (Computer Supported Ubiquitous Learning) Environment: Everyday ubiquitous learning informed by the theories of authentic learning (Brown, Collins & Duguid, 1989), situated learning (Lave, & Wenger, 1991) and learning by doing (Schank, 1995).

Formal Learning: Hierarchically structured, chronologically graded educational system running from primary through to tertiary institutions.

Informal Learning: Unstructured learning that allows persons to acquire attitudes, values, skills and knowledge from daily experience, within the individual's environment (i.e., family, friends, peer groups, etc.).

Lifelong Learners: Self-regulated learners, characterized as demonstrating perseverance, initiative, and adaptive abilities. Self-regulation relates to an ability to recognize a need for further learning as well as to be proactive in gaining access to and accomplishing learning.

Lifelong Learning: A holistic vision of learning in different contexts (formal, non-formal and informal) and throughout life, based on the evolution of provider-driven education toward personalised learning and aiming at improving knowledge, skills and competencies within a personal, civic, social and/or employment-related outlook.

Non-Formal Learning: Learning that takes place through education organized for specific learners with specific learning objectives, outside the formal established system.

QR (Quick Response) Code: A bidimensional code (it displays information in both vertical and horizontal directions) that can hold larger amounts and different kinds of contents (e.g., website addresses, texts, numerical information, contact details) than a normal bar code (monodimensional). The information stored in a QR code can be readily decoded and accessed by a mobile device with an embedded camera and free code reading software installed.

QRcode Format: A technology-enhanced learning format to be implemented in a learner-

centred learning environment to offer inclusive, personalised (different learning styles and goals) and flexible (anytime, anywhere) learning by the integration of paper-based and digital learning materials through QR code.

Ubiquitous Learning: Wireless learning supported by a large number of cooperative small nodes with computing and/or communication capabilities (e.g., handheld devices, sensor network nodes, contact-less smart cards, RFID and QR codes) and characterised by high mobility and embeddedness.

Video Considerations for the World Language edTPA

Pete Swanson

Georgia State University, USA

INTRODUCTION

For decades in the United States, teacher education has been both a political and social focus. As part of President Lyndon B. Johnson's War on Poverty, Congress passed the *Elementary and Secondary Education Act of 1965* (ESEA) in 1965 (P.L. 89-10). This six-part groundbreaking federal legislation placed an emphasis on equal access to education while setting high standards for academic performance and demanding accountability from schools and districts within a framework of six titles. Additionally, the ESEA funded primary and secondary school education, with the goal of decreasing the achievement gap. A year later, two amendments were proposed and passed: Title VI – Aid to Handicapped Children and Title VII – Bilingual Education Programs. At the turn of the new millennium, the landmark legislation was reauthorized by the George W. Bush administration and retitled as *No Child Left Behind* (NCLB, U.S. Department of Education, 2002).

The unfunded mandate demanded even more rigorous testing and accountability of k-12 student learning and included foreign language as part of the core curriculum. While the legislation's philosophical merits (e.g., a highly effective teacher in every classroom) were difficult to dispute, researchers criticized NCLB because it narrowed the k-12 curriculum and prioritized reading, mathematics, and science instruction over

non-tested content areas, such as foreign languages (Rosenbusch, 2005; Rosenbusch & Jensen, 2004). Additionally, teachers had to be considered *highly qualified*. That is, educators in public schools had to have: 1) a bachelor's degree, 2) full state certification or licensure, and 3) prove that they know each subject they teach (U. S. Department of Education, 2004).

When the legislation was reauthorized by the Obama Administration, the law demanded further scrutiny of schools and practitioners. *Race to the Top* required states to measure beginning and veteran teacher effectiveness in order to receive full federal funding (U.S. Department of Education, 2009). Eager to secure federal funds, states began to pass legislation that centered on pre-service teacher preparation and certification standards, emphasizing teacher performance and effectiveness at the state level (e.g., Georgia Professional Standards Commission, 2014; Illinois State Board of Education, 2012). As funding was awarded, states required to use student learning as evidence in teacher evaluation practices (Darling-Hammond, 2012), and in many states throughout the country, pre-service teacher candidates have to demonstrate "the results of classroom processes, such as impact on student learning" (Goe, Bell, & Little, 2008, p. 4), often through teacher performance assessments.

In December 2015, Congress reauthorized the law, now known as the *Every Student Succeeds*

Act (ESSA). Maintaining the rigor of its predecessors, the new legislation leaves the majority of the details regarding teacher education, qualifications, and certification procedures up to the states (U.S. Department of Education, 2015). Aligned with the federal legislation, a new national teacher portfolio, edTPA, has been developed and pilot tested in a variety of states. However, while novel, this new externally-reviewed portfolio is problematic (Hildebrandt & Swanson, 2014), especially in the area of assessment of learning. In this chapter, the authors present edTPA in the context of world languages and then discuss how the Integrated Performance Assessment can be used as teacher candidates develop their portfolios in order to successfully pass edTPA.

BACKGROUND

Over the past 60 years, educational legislation can be categorized into four distinct topics (Cochran-Smith, 2000): teacher attributes (early 1950s to late 1960s), teacher effectiveness (late 1960s through the mid-1980s), teacher knowledge (early 1980s and continuing through the 1990s), and teacher outcomes (2000 to present). Currently, as promoted by legislation, the goal for education in the US is improving student learning, and the measurement of teacher effectiveness is a critical component, which as Muijs (2006) noted, remains challenging.

Teacher Portfolio Assessment

For decades, pre-service teacher candidates' performance as novice educators has been measured via portfolio assessments. *The Teacher Work Sample*, developed by Renaissance Partnership for Improving Teacher Quality (2002), required teacher candidates to create an assessment plan, provide evidence of instructional decision making, use student learning to adjust their teaching, interpret student data, and communicate with

others about students' progress. A few years later, the *Performance Assessment for California Teachers* (PACT) was designed to measure the candidate's knowledge, skills and ability to teach and assess k-12 students (Sato, 2014). Grounded in the National Board for Professional Teaching Standards processes for veteran teachers, the PACT served as the basis for the development of edTPA (Sato, 2014.)

edTPA

Developed by the Stanford Center for Assessment, Learning, and Equity (SCALE) at Stanford University, edTPA is a nationally-available performance assessment of novice educators' readiness to teach in 27 different content areas (SCALE, 2013). Working in conjunction with the American Association of Colleges for Teacher Education and administered by Pearson, edTPA can be administered across institutions and reliably scored by experts in teaching (Sato, 2014). Presently, edTPA is in various stages of implementation in 666 Educator Preparation Programs in 36 states and the District of Columbia participating in edTPA (American Association for Colleges of Teacher Education, 2016) in order to inform initial teacher licensure and certification decisions. For example, Hawaii is going to require a performance-based assessment such as edTPA for teaching candidates beginning in 2017, while Georgia and Illinois began requiring edTPA for certification purposes in September 2015.

Typically, portfolios such as edTPA are developed during a teacher candidate's final field placement, also known as student teaching. The edTPA focuses on three areas: (1) Planning for Instruction and Assessment, (2) Instructing and Engaging Students in Learning, and (3) Assessing Student Learning. World Language teacher candidate effectiveness is measured by thirteen 5-point Likert-scale rubrics. Thus, total scores range between 13 to 65 points. The 5-point scale describes teacher candidates' knowledge and skills

T

ranging from individuals who are not ready to teach to very well-qualified individuals who are ready to teach (SCALE, 2013). It is important to note that beginning teachers are not expected to be in the advanced range of the rubrics.

States are able to determine the levels to which teacher candidates must perform on edTPA and most teacher assessments. For example, a qualifying score of 29 for the World Language edTPA was set in Georgia for Fall 2015 enactment (Georgia Professional Standards Commission, GAPSC, 2015). In 2017, the required score in Georgia will increase to 32 for World Language teacher candidates (GAPSC, 2015). Other states have set cut scores as well: Washington (30), Illinois (31), and New York (35).

Research on the World Language edTPA shows that of the three tasks, teacher candidates “were most successful in the planning tasks and least successful in the assessment tasks” (Hildebrandt & Swanson, 2014, p. 584). Such findings may be explained by what takes place in traditional world language teacher education programs. That is, teacher candidates have ample opportunities to plan for instruction and even teach lessons with students in k-12 schools when participating in field placements like practica and student teaching. With respect to practica placements, teacher candidates observe teachers of record for pedagogical, classroom management, and even assessment purposes. Nevertheless, the teacher candidates are not given access to student data. During their field placement, student teaching, teacher candidates have access to k-12 student data because they are in charge of the classroom typically, but it is during student teaching when teacher candidates develop their edTPA dossiers. Thus, prior to student teaching, teacher candidates do not have sufficient opportunities to collect and analyze data, which is required by edTPA. By the time they have access to student data, it is too late for them to learn how to analyze and write up their findings.

BEST PRACTICES IN WORLD LANGUAGE ASSESSMENT OF STUDENT LEARNING

The teaching and learning of world languages has seen a paradigm shift in recent years. Once known as teaching the four skills (i.e., reading, writing, listening, and speaking) in the target language, world language instruction and assessment is now conceptualized in the communicative language teaching approach that focuses on the three modes of communication: interpretive, interpersonal, and presentational (World-readiness Standards for Foreign Language Learning, 2015). Best practices in language teaching for proficiency in the target language places an emphasis on developing and demonstrating proficiency through performance-based assessments. Through such assessments, students can work individually or collaboratively, use their collection of skills and knowledge to create a response to a prompt (complex questions or situations) or a product that can have more than one correct response (Liskin-Gasparro, 1996, 1997; Wiggins, 1998). Performance-based assessments reflect the tasks and challenges language learners will face in real world scenarios.

Student Proficiency Assessment in the Target Language

The Integrated Performance Assessment (IPA) serves as an evaluation of student ability in the target language that is used as a cluster assessment featuring three tasks with one task in each of the three modes of communication (Adair-Hauck, Glisan, Koda, Swender, & Sandrock, 2006). The IPA is a multi-task assessment conceptualized within a single thematic context. A graphic representation of an IPA is presented in Figure 1. First, language learners complete an interpretive task (e.g., reading). Afterward they use the information from an interpersonal task (e.g., conversation) before they summarize their learning with a pre-

sentational task. In other words, language learners view, listen to, and/or read authentic texts in the target language, interact with learners in the target language in oral and written form, and then present in oral and written form to audiences of listeners and readers.

USING VIDEO AND VIDEO CONSIDERATIONS

Teacher Candidate Skills Using Video

Teacher candidates working on the edTPA possess a wide range of experiences using technology in the classroom. Some have never video recorded themselves teaching before whereas others have completed class assignments which required them to video record their teaching and reflect upon its effectiveness. While it may be an awkward process for students to watch themselves on camera, research supports using video recording as

a powerful pedagogical tool to facilitate teacher candidates' self-reflection and growth (Baecher, McCormack, & Kung, 2014; Calandra, Brantley-Dias, Lee, & Fox, 2009; Danielowich & McCarthy, 2013; Tripp & Rich, 2012).

Teacher preparation programs also vary widely when it comes to the degree to which technology is incorporated into required coursework for pre-service teachers. Some teacher preparation programs mandate that their teacher candidates pass a dedicated technology course and other programs embed technology throughout the curriculum. Despite the wide continuum upon which these pre-service teachers fall regarding technology skills in the classroom, successful recording is essential for passing edTPA and cannot be avoided.

Securing Parental/Guardian Consent

An important prerequisite to the recording phase is garnering approval from parents/guardians of the students in the focal class that has been selected. Once teacher candidates have identified the focal

Figure 1.

class that they will record for edTPA, it is imperative that they immediately notify school administration, their k-12 cooperating teacher, students in the focal class, and their parents/guardians about the recording process and requirements. If school administrators and/or cooperating teachers refuse to allow a teacher candidate to record in their schools and/or classrooms, university supervisors will be required to assign new placements. A natural consequence of this type of logistical problem is that teacher preparation programs may begin to narrow the scope of schools that they place their student teachers in for their field experiences, based on prior consent for, and experience with video recording.

Many teacher preparation programs have developed their own video recording permission forms for teacher candidates' use on the edTPA. It is important to note, though, that while some schools require parents/guardians to sign a school specific consent form for video recording at the beginning of each school year, this form does not include recording for edTPA purposes. In the event that some parents/guardians do not consent to have their child video recorded for edTPA, the teacher candidate must avoid capturing these non-consenting students on camera. However, it is essential that all students, regardless of whether their parents have consented to the recording or not, receive the same quality instruction during the learning segment.

In order to provide all students with the highest quality instruction, while respecting non-consenting parents' wishes, teacher preparation programs often recommend that teacher candidates temporarily reconfigure the classroom into two distinct sections. In one section of the room the teacher candidate would place all of the students whose parents have provided recording consent. Those students for whom the teacher candidate has not been given recording permission should be placed in a different section of the classroom, which is outside of the camera's view. Tripods can be useful tools when student teachers face a situation where not all of their students have gotten parental consent to be recorded. At Georgia

State University, the foreign language education university supervisor recommends that teacher candidates use a tripod to position the camera at an angle that focuses on the consenting students. This way, the teacher candidate can walk about the room freely, and engage with all students, without fear of inadvertently capturing a non-consenting student on camera. In the unlikely case that a non-consenting student accidentally appears on the video, teacher candidates may blur out the image of the student's face.

Minimizing Teacher Candidate Anxiety

As one might imagine, teacher candidates are typically most anxious during the recording phase of the edTPA. There are myriad reasons why the video recording process and submission can be anxiety-provoking for these novice teachers. Students in the Georgia State University foreign language education program who recently completed the edTPA reported the following concerns about the recording phase: technological issues, such as ensuring that the camera's batteries are sufficient to record the entire class period; students' sensitivity to the camera, for example, students misbehaving to *show off* for the camera; the pressure to produce the best quality video of excellent teaching which is highly engaging to students; and factors outside of their control which could come to bear on the video recording process, such as fire drills or other interruptions that could negatively affect the instruction. While these potential issues cannot be completely mitigated, university supervisors and cooperating teachers in the k-12 schools can collaboratively assist teacher candidates by offering suggestions based on past experiences working with video cameras in the classroom for edTPA.

Vital Considerations for Video Recording

There are several common technical issues that teacher candidates deal with when working on the edTPA. Although the edTPA website offers

some resources to teacher candidates vis-à-vis the recording process, teacher candidates may not examine them carefully enough. At Georgia State University, foreign language teacher candidates are provided copies of important edTPA documents, such as the edTPA handbook, evidence chart, and video formatting guidelines. To underscore the importance of avoiding technical pitfalls, the university supervisor reiterates the technical elements in seminar sessions as well as reminder emails and individual conferences with teacher candidates during the entire edTPA process.

One of the most important pieces of advice for world language teacher candidates regarding edTPA is to practice with the recording equipment in advance of the official recording. Recording a lesson that is not part of the learning segment for edTPA can be valuable for many reasons. First, the teacher candidate will have an opportunity to face any discomfort or fears he/she may have with recording their teaching. The high stakes nature of the edTPA assessment and its consequences on teacher certification can be debilitating to some teacher candidates who only want to do their best. If teacher candidates are able to desensitize themselves (and their students) to the camera during the practice recording, everyone should be more comfortable during the official recording. Likewise, pre-service teachers may feel more at ease after having the opportunity to work with the camera equipment to ensure that the recording quality is sufficient. Teacher candidates can breathe a sigh of relief once they rehearse with the equipment and the audio is clear and the video shows student engagement and growth.

Teacher candidates should review both the mock recording and the official one to ensure that they meet all edTPA video requirements. Teacher candidates should select two short clips which highlight the best moments of their teaching during the learning segment (which is comprised of three to five connected days of instruction united by a central focus). These clips must be no more than fifteen minutes total and the two files combined must be less than 300 MB total in size (Pearson, 2014). The relatively small file size requirements

mean that recording in standard definition instead of high definition is recommended, if possible. If the recording device does not offer the option to record in standard definition, teacher candidates can reduce the resolution to either “320 x 240” or “640 x 480” as another avenue to meet the file size requirement (Pearson, 2014). As a last resort, large video files can be compressed to condense the file in order to satisfy edTPA’s constraints but this is not preferable due to technical issues that could potentially occur during the compression process.

In addition to file size specifications, edTPA will only accept video files in the following formats: *flv*, *asf*, *qt*, *mov*, *mpg*, *mpeg*, *avi*, *wmv*, *mp4*, and *m4v* (Pearson, 2014). This stipulation is made to ensure that Pearson’s portfolio reviewers will be able to access the teacher candidates’ video files on their own computers. Consequently, at Georgia State University, the foreign language education university supervisor recommends that teacher candidates open their video files on at least three different computers to avoid a potential pitfall where the Pearson reviewer is unable to open a file on his/her computer. In the event that a Pearson reviewer is unable to open a file, the teacher candidate would receive a condition code for that task, and the entire portfolio would not be scored, requiring a resubmission.

Other technical considerations for video recording include various filming techniques. First, edTPA mandates that the clips be “continuous and unedited, with no interruption in events” (Stanford Center for Assessment, Learning, & Equity, 2015, p. 19). That is to say, the submitted video files cannot be spliced or edited in any way. No sophisticated features such as the title or even opening and closing credits are permitted (Stanford Center for Assessment, Learning, & Equity, 2015). For this reason, teacher candidates are advised to record each day of instruction during the learning segment so that they will have ample options to select from for the final video clips.

Secondly, the two video files must include interactions between the teacher candidate and students as well as student-to-student exchanges.

T

As a result, it can be advantageous for teacher candidates to use a tripod to record whole class interactions but enlist the assistance of a video operator (e.g. the cooperating teacher) to record small group work during the lesson. However, it is paramount that the video operator be well equipped to use the video recording device properly. Since the video clips must be continuous and unedited, the video operator must be cognizant of keeping the video running continuously. While it may be tempting for the video operator to start and stop the recording while moving throughout the classroom, this will cause problems when it comes to selecting a continuous clip.

Likewise, video operators must be mindful of placing a video camera's microphone close enough to capture small group interaction clearly without also recording background noise that could interfere with audio quality. On the world language edTPA, teacher candidates must submit video clips that showcase their students using the language interpersonally, often in small group or paired activities. Strategic placement of the video recording device during these small group exercises is critical to ensure that the focal students can be heard clearly using the target language. If the video clips capture too much background noise, or if the videorecorder is placed too far away from the focal students, it will be nearly impossible to distinguish their speech. When teacher candidates have the opportunity to practice with the video recording device in advance, they then have a better idea of how to strategically place the device and move it around to capture optimal sound quality during the recording phase of the official submission.

Peer Review to Avoid Condition Codes

It is important for university supervisors and k-12 cooperating teachers to assist teacher candidates, particularly with the video recording process, to avoid a costly mistake such as a condition code

which would render the entire portfolio unable to be scored, requiring resubmission. Therefore, at Georgia State University, a peer review assignment is a mandatory component before final submission. During the peer review phase, teacher candidates open their assigned classmate's files and check that all files open properly and comply with edTPA's requirements. While the peer reviewers are not able to offer suggestions on the content of their classmate's portfolio, they are allowed to check for technical issues, such as a corrupt file or a file that is formatted incorrectly. Moreover, reviewing their classmate's portfolio may cause them to notice that a document is missing or formatted incorrectly in their own portfolio. The peer review process happens during the last weekend before official submission, so that each teacher candidate has a few days to review their peer's feedback and make any last-minute changes to improve their own portfolio.

All of these video recording strategies are crucial components for teacher candidates' success on the world language edTPA. The stakes are so high for edTPA that receiving a condition code for even one video means the teacher candidate will be required to resubmit one or more of the tasks at an additional cost. Beyond the financial toll, the resubmission process itself can be time consuming, depending upon how many tasks need to be redone. Official scoring reports often take three to four weeks to receive, which could potentially create timing issues for program completion and state certification. As a result, Georgia State University world language teacher candidates are required to submit their official edTPA portfolio by week ten to account for the extra time that could be needed to resubmit in order to receive a passing score by the end of the semester. Without achieving the state determined qualifying score on the edTPA, teacher candidates cannot be recommended for teacher certification, and therefore, may be held back from becoming employed by a school district.

FUTURE RESEARCH DIRECTIONS

edTPA is a relatively new teacher performance assessment on the US educational landscape and there is much to learn about it. At this moment, there is a dearth of research on the World Language edTPA (Hildebrandt & Swanson, 2014, 2016). It would be informative to learn more about how world language teacher education programs have been restructured since edTPA was approved for licensure decisions in so many states. Additionally, more empirical evidence is needed for multiple reasons ranging from programmatic improvement decisions to helping teacher candidates prepare quality dossiers. It would also be helpful to know more about how teacher education programs provide remediation to teacher candidates who are initially unable to pass one or more sections of the edTPA. At the moment, only quantitative research methods have been used to examine teacher candidate performance on the World Language edTPA. Qualitative and mixed methods research designs would provide important insight into this new high-stakes and costly assessment at a time when testing costs to become a teacher are approximately \$1000 in Georgia (Hildebrandt & Swanson, 2014).

CONCLUSION

Since the mid-1960s, the ESEA legislation has been an integral part of US curriculum and instruction. As noted earlier, the law focused on not only equal access to education but also setting high standards for academic performance while demanding accountability from schools and school districts. Every president since then has worked to reauthorize the legislation and arguably the most controversial reauthorization is known as *No Child Left Behind* (NCLB, U.S. Department of Education, 2002). This mandate sought more rigorous testing and accountability of k-12 student learning and included foreign language as part of

the core curriculum. Years later the Obama administration's initiative, *Race to the Top*, further scrutinized the educational process and mandated that states begin measure beginning and veteran teacher effectiveness to receive full federal funding (U.S. Department of Education, 2009).

Now, edTPA has been rolled out in more than half of the states and is a cause for concern, especially given that pre-service world language teacher candidates in many states have to successfully pass edTPA in order to receive teacher licensure (Hildebrandt & Swanson, 2016). Thus, we strongly recommend that teacher preparation faculty members take the time to work with teacher candidates specifically on the aspects of video recording in the classroom. It is important to first gain parental permission to film adolescents in schools and it is equally important for teacher candidates to rehearse such aspects as camera and tripod placement, framing angles to show students, lighting, audio quality so that students can be heard well, all of which will help reduce teacher candidate anxiety and improve overall video quality.

In sum, edTPA is a high-stakes teacher candidate assessment and care must be taken when developing portfolios for external review. Research shows that teacher candidates have been found to score lower on the assessment task of the portfolio (Hildebrandt & Swanson, 2014), and the integrated performance assessment appears to have merit when teacher candidates develop their edTPA dossiers.

T

KEY TERMS AND DEFINITIONS

Central Focus: As defined by SCALE, the important understandings and core concepts that students will develop during the teaching of the learning segment.

Communicative Language Teaching (CLT): An approach to language instruction that prioritizes target language interaction as both the overarching goal as well as an avenue for accomplishing that goal. This approach focuses primarily on the development of students' communicative competence in a meaningful cultural context.

edTPA: The first nationally available subject-specific performance-based assessment adopted by many U.S. states as a means to measure teacher candidates' developing skills and knowledge.

Integrated Performance Assessment (IPA): A standards-based and performance-based assessment which incorporates three tasks, aligned with a common central focus, that focuses on each of the following modes of communication: interpersonal, interpretive, and presentational.

Learning Segment: As defined by SCALE, a series of three to five days of consecutive instruction centered on a common central focus, marked by identifiable beginning and ending points.

Modes of Communication: Based on ACTFL's stance that communication occurs in three modes: interpersonal, interpretive, and presentational.

Pre-Service Teachers: Also known as teacher candidates, this term is used to describe student teachers who are enrolled in a teacher preparation program and working toward teacher certification. They complete supervised field-based teaching experiences with the support and mentorship of university faculty and K-12 cooperating teachers.

Efficient Optimization Using Metaheuristics

T

Sergio Nesmachnow

Universidad de la República, Uruguay

INTRODUCTION

Nowadays, many real-world problems are intrinsically complex. Optimization is a process that deals with hard problems arising in many scientific, academic, and commercial applications. Many optimization problems are difficult to solve, because of having large solution spaces, handling complex functions and hard constraints, or managing large volumes of data. Traditional computing methods are not useful in practice for solving these hard problems, because they demand very large execution times when solving realistic instances.

Metaheuristics are soft computing methods that allow computing accurate solutions for hard-to-solve problems in reasonable execution times. Metaheuristics are conceived under simple paradigms to take advantage of tolerating imprecision, uncertainty, and approximation in the problem data. They can handle partial information and non-exact solutions in order to compute accurate solutions for optimization problems. These features make metaheuristics highly valuable techniques, as they allow meeting realistic resolution times in many application areas, from informatics to industrial and commercial.

Metaheuristics were proposed almost thirty years ago, and nowadays this research area is consolidated. Many metaheuristic proposals have been formulated, regarding both theoretical models and applications. This chapter provides an insight into the main concepts, advances, and results in the field of metaheuristics for efficiently solving optimization problems. A general view of most well-known metaheuristics is presented and the main applications of metaheuristics in nowadays real-world problems from several domains is described. Finally, the main current and future research lines in the field are also summarized.

DOI: 10.4018/978-1-5225-2255-3.ch669

BACKGROUND

Metaheuristics are high-level soft computing strategies that define algorithmic frameworks and techniques to find approximate solutions for optimization problems (Blum & Roli, 2003; Talbi, 2009). Many efficient and accurate metaheuristics have been proposed, which can be applied to solve a variety of optimization problems underlying many applications in science/technology, industry, and commerce.

Metaheuristics Concepts: Definition and Classification

Metaheuristics were originally proposed as high-level problem-independent strategies to coordinate several heuristic search methods, which can be instantiated to solve hard problems. This definition has broadened to include a wide range of search and learning processes (including shaking, construction/deconstruction, adaptation, swarming and collective behavior, hybridization, etc.) applied to improve the search.

The heuristic components in a metaheuristic are conceived to be applied in an intelligent way, providing accurate and balanced methods for diversification and intensification. These two concepts are very important to guarantee the efficacy of the search: *diversification* refers to achieving a good exploration pattern for the search space, providing a reasonable coverage and avoiding stagnation in local optima; *intensification* means exploiting or improving already found accurate solutions to increase their quality.

Regarding the number of solutions handled, metaheuristics are classified in two classes: *trajectory-based* and *population-based*. Trajec-

tory-based metaheuristics work with a single solution, which is replaced by another (often the best) solution found in its neighborhood. The search is characterized by a trajectory in the space of solutions. Trajectory metaheuristics allow quickly exploiting solutions, thus they are referred as intensification-oriented methods. On the other hand, population-based metaheuristics work with a set of candidate solutions, which are modified and/or combined following some common guidelines. Some solutions in the population are replaced by newly generated solutions (often the best). These methods are characterized as diversification-oriented, because having multiple solutions allows significantly increasing the exploration capabilities.

Other classification criteria for metaheuristics are related to specific features of the search strategy, for example: memory vs. memory-less, or dynamic vs. static objective function.

Metaheuristic Techniques

Trajectory-based metaheuristics include many well-known techniques from the early years of this area:

- **Simulated Annealing (SA):** Probabilistically allows moving to a solution with worst objective function value, trying to escape from local optima (Kirkpatrick et al., 1983). SA is inspired on the annealing process of metals and it was the first metaheuristic proposed, although the term “metaheuristic” was not used in those years.
- **Tabu Search (TS):** Enhances a local search strategy by using memory to store information about visited solutions. To promote diversification, returning to recently visited solutions is not allowed. TS was introduced by Glover (1986), who first used the term “metaheuristic”.
- **Greedy Randomized Adaptive Search Procedure (Feo and Resende, 1995):** A metaheuristic which greedily selects com-

ponents to construct a solution, and then applies a local search to improve it.

- **Variable Neighborhood Search (Mladenovic & Hansen, 1997):** Local search techniques based on using different neighborhood structures during the search.
- **Iterated Local Search (Lourenço et al., 2002):** Uses a hill-climbing to find local optima and a stochastic perturbation/restart strategy to prevent the search getting stuck in local optima.

Population-based metaheuristics include techniques that use cooperation in the search:

- **Evolutionary Computation (EC):** Emulates the evolution of species in nature by applying stochastic operators (recombination and random changes) on a population. A selection-of-the-best strategy guides the search to high-quality solutions. EC includes Genetic Programming (Koza, 1992), Evolution Strategies, and Evolutionary Algorithms (EAs) (Goldberg, 1989).
- **Swarm Intelligence (SI):** Uses agents to perform explorations while they interact with neighbors and the environment, based on the collective behavior of self-organized systems. Agents have limited search capabilities, but an “intelligent” pattern emerges in large swarms. SI include Ant Colony Optimization (ACO), emulating the behavior of ants foraging for food (Dorigo, 1992), Particle Swarm Optimization (PSO), simulating flocks of birds (Kennedy & Eberhart, 1995), Artificial Immune System (DasGupta, 1998), and the recently proposed Bacterial Foraging, Fish/Glowworm Swarm, Firefly Algorithm, Cuckoo Search, and Bee Algorithms.
- **Evolutionary-Inspired Metaheuristics:** Apply an evolutionary search, with different features. Estimation of Distribution Algorithms learn by building/sampling probabilistic models of promising solu-

tions (Larrañaga & Lozano, 2002). Scatter Search/Path Relinking applies a specific recombination and ideas from TS (Glover, 1999). Differential Evolution is specialized for optimizing real functions (Storn & Price, 1997). Harmony Search (HS) emulates the improvisation of musicians (Geem et al., 2001). Memetic Algorithms includes a local search phase after the evolutionary operators (Moscato, 1999).

Hybrid models are used to improve the search capabilities of metaheuristics. Strong hybrid metaheuristics are constructed by including problem-oriented representations and operators. Weak hybrids are built by combining several methods to improve the search. An efficient cooperation is achieved by exchanging a small set of solutions or statistical values (Talbi, 2002).

Parallel metaheuristics allow enhancing and speeding up the search by using several computing elements. They reach high quality results in short execution times, even for hard-to-solve optimization problems.

The main models for parallel trajectory metaheuristics are:

- **Parallel Multi-Start:** Launches several instances, which may be independent/co-operative, start from the same/different solution(s), use the same/different parameters, etc.
- **Parallel Moves:** Distributes the current solution to several processes, each one explores by applying a search based on its candidate solution and the results are returned to the main process.
- **Move Acceleration:** Evaluates several moves in a parallel centralized way, by parallelizing the objective function using an aggregation approach.

The main models for parallel population metaheuristics considers the population organization:

- **Master-Slave:** Applies a hierarchical functional decomposition: a master process performs the evolutionary search, and controls a group of slave processes that evaluate the objective function, which often requires larger computing time than the search operators.
- **Distributed Subpopulations:** Splits the population in subpopulations, each one running a sequential metaheuristic. The solutions only can interact within their subpopulation. A migration operator exchanges some selected solutions among subpopulations, introducing a new source of diversity.
- **Cellular:** Uses an underlying spatial structure for the population. Interactions are restricted to neighbor solutions, and characteristics gradually propagate through the grid. This feature is useful to provide diversity in the population, often improving the search.

The research on parallel metaheuristics is very important nowadays, when large instances of real-world problems are solved (Alba et al., 2013).

STATE OF THE ART: CURRENT RESEARCH LINES

Issues

The main research issues are related to methodology, algorithms, and applications.

Methodology

Methodology is well regarded and needed for a comprehensive view of the field. Providing mathematical foundations and theoretical analysis for metaheuristics, such as the convergence for SA (Laarhoven & Aarts, 1987), EC (Goldberg, 1989), PSO (Clerc & Kennedy, 2002), and ACO (Gutjahr, 2010) is important. Theoretical convergence is

desired, but because it is often only guaranteed in inefficient times, analysis based on computing hitting-time or takeover-time are relevant to determine the applicability of metaheuristics as problem solvers. Studying the dynamic behavior of metaheuristics and landscape analysis for specific problems are also relevant.

Parameter tuning of metaheuristics is also important. It significantly impacts on both efficiency and accuracy, and even can prevent metaheuristics to be accepted into real-world software. Specific methodologies have been proposed for fine-tuning metaheuristics, trying to move this task from art (i.e., usually following rules-of-thumb) to science (i.e., following a sound approach) (Birattari, 2009). This issue is related to the more general one about robustness and sensitivity of metaheuristics.

Developing methodologies for the statistical analysis of results and designing benchmark problems for evaluating and comparing both existing algorithms and new proposals is also very important (Bartz-Beielstein, 2010).

Algorithms: Design and Implementation

Traditional metaheuristics, proposed more than twenty years ago, are firmly established as problem solvers. Their main algorithmic features have been studied, but several design alternatives have led to not-so-well-explored variants, for which their actual contribution is yet to be demonstrated. Most classic metaheuristic are implemented in the software frameworks available today.

Many recently proposed metaheuristics are not consolidated yet. Among them, we can mention Harmony Search, Artificial Bee, Cuckoo Search, Firefly Algorithm, etc., which take inspiration in different natural/physical processes for problem solving. The application of these novel methods to different hard-to-solve optimization problems is needed to evaluate the contribution of each proposal. The emergence of many “new” metaheuristics is not free from controversy.

A whole line of research is open concerning the design and implementation of metaheuristic

techniques to solve specific problem classes, including multiobjective optimization, stochastic/uncertain optimization, constraint handling, very large scale optimization, and others.

Applications

Although originally proposed to solve combinatorial optimization problems, nowadays metaheuristics are useful tools to solve real-life problems arising in diverse application domains.

Many works have focused on solving academic optimization problems related to resource assignment, routing, set covering/partitioning, etc. in several variants: discrete combinatorial problems, continuous, multi-objective, and dynamic problems.

Real-world problems from science, industry and commerce, have also been solved using metaheuristics. In *automation*, metaheuristics are applied as accurate/efficient learning techniques helping to reduce the need for human presence. In *bioinformatics*, metaheuristics are efficient techniques to deal with computationally-expensive problems that manage very large amount of data in this emergent scientific field (sequence alignment, drug design, genome assembly, protein structure). In *engineering*, metaheuristics are useful for designing systems with many components, complex functions, and large design spaces (aerodynamic optimization, signal and image processing, machinery design, electronics, hydraulic networks). In the area of *information processing*, the fast exploration of metaheuristics significantly help with the challenge of dealing with huge volumes of data (feature selection, classification/clustering, data mining, natural language processing). In *manufacturing and industry*, metaheuristics allow increasing competitiveness in nowadays globalized economy (warehouse location, packing, assembly line problems). In *planning and scheduling*, metaheuristics have a major impact on the productivity and quality of service by accurately deciding how to commit resources to a group of tasks in very reduced execution times. Metaheuristic

tics are also useful optimization methods in *routing and logistics*, to manage the flow of resources for large complex scenarios. In *telecommunications*, metaheuristics have great impact on addressing the main challenges from classic wired to modern wireless cellular/vehicular/sensor network infrastructures, including dealing with large-sized scenarios, need for real-time results, etc.

Metaheuristics have also been successfully applied in energy optimization, medicine, military applications, economy and finance, and many other areas, frequently using multiobjective, hybrid, and parallel metaheuristics. These facts show the growing maturity of the research in metaheuristics, and allow concluding that many real-life problems will be solved using metaheuristics in the near future (Nesmachnow, 2014).

Controversies

The metaheuristics field has developed fast, but some issues are controversial, including unconvincing methodologies used for the experimental evaluation and the emergence of many “new” methods.

Regarding the experimental evaluation, it has been noticed that many published articles do not provide a proper experimental analysis, e.g., the authors only confront the results against simple ad-hoc heuristics, or they even do not provide a comparison at all. Often the comparison of metaheuristic is not conducted by applying standard metrics and a proper statistical methodology. In some cases, researchers apply metaheuristics to very small problem instances or even to not hard-to-solve optimization problems. Maybe the lack of an accepted generic framework for performance assessment is behind these shortcomings when studying metaheuristics on real-world problems. However, general guidelines for statistical evaluation and analysis exist, thus researchers have no excuses to present poorly studied results.

Several “new” metaheuristics have been proposed, inspired on many natural/physical phenomena (e.g., Glowworm Swarm Optimization (GSO),

Gravitational Search, Intelligent Water Drops (IWD), Bat Algorithm, etc.). Some researchers have a critical view of these new techniques, mostly based on the improper use of metaphors or phenomena emulation to justify the proposals (Sörensen, 2015). Critics argue that many new metaheuristics are only reformulating previous methods, introducing small variants on classic metaheuristics. In some cases, the new variants are not properly evaluated, making difficult to determine the real contribution to the field. For example, while SI methods are based on emergent intelligence, the new GSO shares several features with ACO and PSO, and it is also strongly related to Firefly Algorithm, Bat Algorithm, and Migrating Birds Optimization. Moreover, it has been argued that techniques like IWD are based on doubtful premises, with few links with reality.

The debate about the HS metaheuristic is a clear example of how some researchers are skeptical about new metaheuristics proposals: Weiland (2010) suggested that HS is a special case of EA; Geem (2010) attempted to refute the critic, and Padbreg (2011) proved that HS is equivalent to an EA with a special crossover operator. A plethora of “new” methods have been recently proposed, including bio-inspired (Generalized Response Surface, Open Source Development Model, Biogeography Optimization, Shuffled Frog Leaping, Invasive Weed Colony, etc.) (Yang, 2008); and based on physics/mathematics (Spiral Optimization, Big Bang–Big Crunch, Gravitational Search, Hysteretic Optimization, Immune Gravitation, Artificial Physics Optimization, Charged System Search, Galaxy Search, etc.) (Biswas et al., 2013). Quantum-computing implementations of metaheuristics are popular too. Some of these “new” algorithms are too similar to each other, and they were published in conferences/journals outside the area. This phenomenon is not new: in the 1990s, several metaheuristics were proposed (Search Space Smoothing, Threshold Accepting, Great Deluge, Demons Algorithm), but they were black-box techniques based on local search/SA, so they did not gain popularity. Anyway, as some

new proposals do not have solid foundations and have not been properly validated, researchers and practitioners should take care when proposing or applying a “new” method to solve specific problems.

Problems

The lack of a general methodological framework for evaluating metaheuristics is a key problem in the field. Although statistical analysis is recognized as a must for metaheuristics evaluation, a well-conceived scientific approach is needed to avoid “craft” procedures for parameter setting and experimental analysis.

Regarding implementations, an important challenge nowadays is designing generic frameworks and software libraries for developing and using metaheuristic algorithms. Here, several crucial aspects should be taken into account, including programming decisions, modularity, reusability, flexibility, and the trade-off between usability and computational efficiency of each implementation. Nowadays, many libraries and frameworks exist, including some comprehensive ones, such as ECJ, EO/ParadiseEO, HeuristicLab, JDeal, MALLBA, and Opt4j (see a full list on Luke (2013)). Nevertheless, more effort is required to conceive efficient and easy-to-use implementation guidelines for generic metaheuristic frameworks.

SOLUTIONS AND RECOMMENDATIONS

When searching for a useful optimization method to solve a problem, a wise idea is to apply a systematic bottom-up approach: starting from a simple solver (i.e., using trajectory-based strategies) and then move to more complex metaheuristics. This approach usually leads to a better understanding of the problem and the capabilities of each resolution technique. When a specific method includes many search operators or paradigms, the contribution

of each component must be studied carefully and systematically.

Another important recommendation to determine the contribution of metaheuristics as optimization techniques is to develop a formal background for studying theoretical properties (i.e. convergence) and metrics. The usefulness of specific ideas, components and/or search operators should be carefully evaluated, for all (especially new) metaheuristics. A formal, component-wise experimentation is crucial to provide a clear understanding of the algorithms.

Recently proposed metaheuristics, based on unconventional search paradigms, should be applied when providing real arguments about how useful are their searching strategies for the class of problem targeted.

Applying a careful methodology for obtaining and analyzing the results in the experimental evaluation of metaheuristics is mandatory (Rardin & Uzsoy, 2001). Important aspects related to metaheuristics evaluation are experiments design, finding appropriate test instances, evaluating numerical efficacy and time efficiency, and clearly presenting and analyzing the results. In any publication, a comprehensive number of problem instances should be solved. Instances must be representative of realistic properties and dimension of real-world problems: analysis performed over few and/or small instances are not useful at all, since they do not provide evidence about the applicability and efficiency of the metaheuristic method. Small toy problems, for which even a random search could compute good solutions, must be avoided. When specific benchmarks exist, they must be used, and the metaheuristics results must be compared against those from the best known methods for solving the problem.

Parameter evaluation tests must be performed on a separated set of problem instances, in order to avoid bias in the experiments (Coy et al., 2001). At least 30 (recommended 100) independent executions must be performed for parameter setting and also for validation experiments. Both numerical

results and execution time should be reported and statistically assessed (McGeoch, 2008). Scalability analyses regarding the problem dimension are recommended.

Statistical methods must be employed to analyze the results. A standard methodology for the statistical analysis of metaheuristics is to apply a normality test (e.g., Kolmogorov-Smirnov/Shapiro-Wilk) to check if the results follow a normal distribution; if so, a Student/ANOVA test must be applied next; otherwise, a non-parametric test (e.g., Kruskal-Wallis/Wilcoxon/Friedman) must be performed. This two-step procedure allows controlling the error of incorrectly rejecting the null hypothesis when it is true, since two independent phases (testing for different null hypotheses), are used. For metaheuristics, usually the result distributions are not normal, so non-parametric tests and median analysis are recommended. A comparative analysis of metaheuristics must be performed using well-known statistical tests and metrics, and considering a set of realistic problem instances.

Regarding implementation, some recommendations oriented to develop efficient and easy-to-use libraries include making the most of modularity and reusability. This strategy allows the user to develop easy implementations, not starting from scratch, and focusing on the specific contributions of his work. C/C++ and Java are the most used languages to develop metaheuristics (Nesmachnow et al., 2015). Object-oriented features of high-level languages are useful, but some of them (inheritance, polymorphism, overloading) usually conspire against efficiency and they should be used carefully. At the end, researchers should not forget that the ultimate goal of any computing technique is to provide a real solution for the problem that should be user-friendly, robust, and able to cope with day-to-day real-world operation.

Nowadays, practitioners and researchers have many resources to address the main concepts about metaheuristics. Excellent books published about the subject are: “Essays and Surveys on Metaheuristics” (Hansen and Ribeiro, 2001),

“Handbook of Metaheuristics” (Glover and Kochenberger, 2003), “Metaheuristics: Progress as Real Problem Solver” (Ibaraki et al., 2005), “Nature-Inspired Metaheuristic Algorithms” (Yang, 2008), “Metaheuristics: From Design to Implementation” (Talbi, 2009), “Handbook of Metaheuristics” (Gendreau and Potvin, 2010), “Essentials of Metaheuristics” (Luke, 2013).

A good practice to evaluate the research on metaheuristics is submitting articles to conferences and journals in the field. Nowadays, several conferences focus in metaheuristics. The most respected ones are Metaheuristics International Conference (11 editions, 1996–2015), Parallel Problem Solving from Nature (12 editions, 1990–2012), and EU/ME Workshop (15 editions, 2000–2015). Younger conferences on metaheuristics are International Conference on Hybrid Metaheuristics (8 editions, 2004–2013), and International Conference on Metaheuristics and Nature Inspired Computing (5 editions, 2006–2014). Specific streams about metaheuristics exist on Operation Research societies like ALIO, EURO, INFORMS, and OR Society. Conferences focused on EC include Genetic and Evolutionary Computation Conference (24 editions, 1985–2015); IEEE Congress on Evolutionary Computation (17 editions, 1999–2015); EvoStar (18 editions, 1998–2015); and Evolutionary Multi-Criterion Optimization (8 editions, 2001–2015). Other relevant conferences are International Conference on Unconventional Computation and Natural Computation (14 editions, 1998–2015); Asia-Pacific Symposium of Intelligent and Evolutionary Systems (19 editions, 1997–2015); International Workshop on Nature Inspired Cooperative Strategies for Optimization (7 editions, 2006–2015); IEEE International Conference on Intelligent Systems (7 editions, 2002–2015); EVOLVE (5 editions, 2011–2015), and International Conference on Theory and Practice of Natural Computing (4 editions, 2012–2015). Conferences on SI and other metaheuristic methods include ANTS International Conference on Swarm Intelligence (9 editions, 1998–2014); International Confer-

ence on Artificial Immune Systems (12 editions, 2002–2013); Learning and Intelligent Optimization (9 editions, 2005–2015); and International Conference on Swarm Intelligence (6 editions, 2010–2015).

Two novel journals focusing on metaheuristics started publishing in 2010: *International Journal of Metaheuristics* and *International Journal of Applied Metaheuristic Computing*. Both journals are still consolidating, thus most articles on metaheuristics are often published on soft computing and related journals: *Soft Computing*, *Applied Soft Computing*, or *IEEE Transactions on Evolutionary Computation*. Other related journals are *Swarm Intelligence Journal*, *International Journal of Bio-Inspired Computation*, *Swarm and Evolutionary Computation*, and *International Journal of Swarm Intelligence*.

FUTURE RESEARCH DIRECTIONS

Several relevant issues about metaheuristics are still in a consolidation stage, while many others emerge as promising lines for actual and future work.

Regarding algorithms, there is still room to contribute in establishing a sound foundation for the search patterns proposed by each metaheuristic, especially for the novel methods proposed in the last years. The importance of the intensification and diversification strategies to efficiently compute accurate results was demonstrated in earlier theoretical works, and now those concepts provide a hint for developing a unified view for metaheuristics. In fact, some researchers are working on this topic. Using theoretical results to design more powerful search strategies is also a promising line of work too.

The design and formalization of frameworks for metaheuristics, including algorithms, metrics, methodologies for the statistical analysis, and

comprehensive benchmarks for different problem classes, is also an important line of research. Formal methodologies should be adopted to design and implement generic software libraries for metaheuristics.

The hybridization of well-known metaheuristics with other search techniques, including heuristics and exact methods, is also a promising field of study. Several important issues emerge in this line of work, including if (and when) it is worth to sacrifice the general capabilities of metaheuristics in order to obtain efficiency or accuracy for solving a given class of problems. Determining how useful is introducing problem knowledge and how to incorporate it in a systematic way is very important too.

Another promising line of work is related to parallel models for metaheuristics. Researchers in this field are trying to conceptualize a unified view of parallel metaheuristics, taking into account the points of view of theory and technology. They are also working on including relevant issues such as using new mobile devices and large computing infrastructures (accelerators, many-core devices, graphic processors, grid and cloud computing).

All the previous features are also valuable regarding the application of metaheuristics on different application domains. In real life, concepts such as hybridization, adaptation, comprehensible implementations, and features such as flexibility, robustness, easy-to-use, and efficiency for interactive/online problems can contribute to make metaheuristics the preferred choice as useful optimization methods.

Finally, a wide field of opportunity is still open concerning the application of metaheuristics to different hard-to-solve optimization problems arising in new technological, industrial, and commercial areas. Multiobjective optimization, dynamic problems, stochastic and uncertainty optimization, interactive or online problems and applications, are among the main lines of research in the field.

CONCLUSION

This chapter provided an insight of the field of metaheuristic techniques and their characterization as methods to solve optimization, search, and learning problems.

Nowadays, metaheuristics have established as useful tools in practice to cope with the complexity of many real-world problems, and this chapter summarized the main ideas, concepts, problems and solutions, and future research direction in the field, in a descriptive way which should be useful to researchers, practitioners, and also newcomers to the area.

KEY TERMS AND DEFINITIONS

Diversification: Exploration of the search space providing a reasonable coverage and avoiding stagnation in local optima.

Intensification: Exploitation of already found accurate solutions to increase their quality.

Metaheuristics: High-level strategies that define algorithms to find approximate solutions for optimization problems.

Parallel Metaheuristics: Models that use several computing elements for enhancing and speeding up the search.

Population Metaheuristics: Methods that work with a set of solutions, which are iteratively modified and/or combined to produce new solutions.

Trajectory Metaheuristics: Methods that work with a single solution, which is iteratively replaced by another one in its neighborhood.

An Essay on Denotational Mathematics

Giuseppe Iurato

University of Palermo, Italy

INTRODUCTION

Denotational Mathematics (in short, DM) is a new discipline which serves as a formal language to lay out and solve the various problems posed, amongst others, by cognitive informatics, software science and computational intelligence. It has been worked out in the last decades by Yingxu Wang (2008a-e, 2009a-c, 2010a-b, 2011, 2012a-b)¹, to whose many works and papers we refer for a wider and more complete information science contextualization of DM and its applications.

In this contribution, we wish to briefly outline, but in a rigorous manner, the main formal structures considered by DM, within the framework of classical algebra of relations. Our exposition is extremely technical and synthetic to allow a faster and clearer overall view of the pivotal mathematical structures of DM, which are *concept algebra*, *real-time process algebra*, *system algebra*, *visual semantic algebra*, *granular algebra*, and *inference algebra*.

In relation to its possible applications to the general context of information sciences, numerical mathematics, as regard continuous context, mainly deals with rational ($\mathbb{Q}$), real ($\mathbb{R}$) and complex ($\mathbb{C}$) number systems, while, as regard discrete context, it deals with natural ($\mathbb{N}$), integral ($\mathbb{Z}$) and binary ($\mathbb{B}$) numerical systems. DM may be considered either from the classical algebra viewpoint (as done here) or from the model theory one². In any case, it mainly deals with *hypercomplex* ($\mathbb{H}$) denotational algebraic systems, which will be defined in the next section 4.

BACKGROUND

Generally speaking, methods of mathematics may be roughly classified into *analytical*, *numerical*, and *denotational* approaches. The analytical approach deals with continuous mathematical objects defined in the real number field ($\mathbb{R}$); the numerical approach deals with discrete mathematical entities defined in $\mathbb{R}$ and in binary systems ($\mathbb{B}$) with iteratively and recursively approximation functions.

However, the domains of recent problems in the emerging disciplines of artificial intelligence, cognitive informatics, brain science, cognitive computing, knowledge science, and computational intelligence require rather new *complex hyperstructures* ($\mathbb{H}$), beyond that of pure numbers in ($\mathbb{B}$) and ($\mathbb{R}$), which just identify the denotational approach.

The requirement for reducing complicated formal problems and solutions to the low-level objects in conventional computing theories and the underpinning of analytical or numerical mathematical means, has greatly constrained the inference and computing ability of both human and intelligent systems.

This has motivated the introduction of transdisciplinary investigations provided by *denotational approach* based on novel mathematical structures for modelling and processing new complex hyperstructures required to be established by cognitive computing and computational intelligence, collectively known just as denotational mathematics (DM).

DM may be viewed as a rigorous formal approach to processing both complex architectures and intelligent formal behaviours in order to cope with the fundamental challenges in understanding, describing, and modelling natural and machine intelligence in general, as well as concept, knowledge and semantics, in particular.

As a counterpart of the classic analytic mathematics, DM encompasses new forms of mathematical structures for dealing with complex objects recently emerged in a very wide range of contemporary disciplines and fields such as cognitive informatics, cognitive computing, abstract intelligence, artificial intelligence, computational intelligence, semantic computing, software science, knowledge science, system science and computing with words.

In recognizing mathematics as the main methodology of all informatics sciences and engineering disciplines³, a set of DM structures have been created in the last decades. DM provides a coherent set of contemporary mathematical means and explicit expressive power for dealing with both complex mathematical objects and long-chains of serial and embedded mathematical operations emerged in multiple modern disciplines.

In DM, not only the mathematical entities are greatly complicated at a formal level, but also the mathematical structures and methodologies are significantly expanded from simple relations and independent functions to embedded relations and serially coupled functions.

In what follows, we outline the chief elements and aspects of the main DM structures, with a view toward their possible applications to information sciences and technology.

THE NOTION OF HYPERCOMPLEX ALGEBRAIC SYSTEM

Generally speaking, an *algebraic system* is a tuple $\Xi \stackrel{\text{def}}{=} (\{A_i\}_{i \in I}; \{R_j\}_{j \in J})$, where A_i is a non-empty set for each $i \in I$, and $\phi \neq R_j \subseteq \prod_{k \in K_j} A_k$ for each

$j \in J$, is a *relation*. If, for instance, $I = \{1, 2\}$ and J is a singleton, then $\phi \neq R \subseteq A_1 \times A_2$ is a *binary (external) relation* with *domain* in A_1 and *codomain* in A_2 ; if $A_1 = A_2 = A$, then R is a *binary (internal) relation* on the *support* A .

For example, a *semigroup* is an algebraic system of the type $(A; R)$, where A is a non-empty set (*support*) and R is a ternary internal relation $\phi \neq R \subseteq A^3$ such that

$$(a, b, c) \in R \wedge (a, b, c') \in R \Rightarrow (c = c') \forall a, b, c, c' \in A \quad (\text{univocity of } R),$$

which verifies the associative law. Often, such a ternary internal relation is written as a function of the type $R: A \times A \rightarrow A$, with $(a, b) \in R$ wrote as aRb .

An algebraic subsystem (or restriction) $\check{Z}'$ of Ξ , is an algebraic system of the type

$$\check{Z}' \stackrel{\text{def}}{=} (\{A'_i\}_{i \in I}; \{R'_j\}_{j \in J}), \quad \text{w h e r e} \\ \emptyset \neq A'_i \subseteq A_i \quad \forall i \in I, \text{ and } R'_j \subseteq \prod_{k \in K'_j} A'_k \text{ with} \\ R'_j = R_j \upharpoonright_{\prod_{k \in K'_j} A'_k} \text{ and } K'_j \subseteq K_j \text{ for each } j \in J. \text{ Like-}$$

wise, starting from $\check{Z}'$, Ξ may be considered as an algebraic extension of $\check{Z}'$. The notion of action of a set G on another set A , may be generalized considering it as an external relation of the type $R \subseteq G \times A$ (Artin, 1991).

Let $\mathcal{F} = (\{A_i\}_{i \in I}; \{R_j\}_{j \in J})$ be an algebraic system. A denotational algebraic hypercomplex system $\mathbb{H}_{\mathcal{F}}$ in the framework $\mathcal{F}$, is an algebraic

systems of the type $\mathbb{H}_{\mathcal{F}} \stackrel{\text{def}}{=} (\{B_k\}_{k \in K}; \{S_l\}_{l \in L})$, where $K = K_1 \cup K_2, L = L_1 \cup L_2$, with $K_1 \subseteq I, L_1 \subseteq J$, $K_1 \cap K_2 = L_1 \cap L_2 = \phi$, $B_k \in \{A_i\}_{i \in I}$ for each $k \in K$, $S_l \in \{R_j\}_{j \in J}$ for each $l \in L_1$, $\left(\bigcup_{k \in K_1} B_k \right) \cap \left(\bigcup_{k \in K_2} B_k \right) = \phi$, and $S_l \subseteq \prod_{k \in K_1^l \cup K_2^l} B_k$ with $K_1^l \subseteq K_1, K_2^l \subseteq K_2$ for each $l \in L_2$. Each $S_l, l \in L_1$, is said to be an internal relation of $\mathbb{H}_{\mathcal{F}}$, while

every $S_i, i \in L_2$, is said to be an external relation with input/output values in $B_k, k \in K_2^i \subseteq K_2$.

In what follows, typical instances of denotational algebraic hypercomplex systems ($\mathbb{H}$) are those of concept algebra, system algebra, and granular algebra, of which we shall give a brief formal explanation. $\mathbb{H}$ is a powerful modelling metaphor for abstract objects and systems, which can be used to elicit and model the essences of complex objects with hyperstructures beyond $\mathbb{H}$, and set.

Typical mathematical objects in $\mathbb{H}$ are such as multi-facet objects, complex relations, perceptual information, abstract concepts, formal knowledge, intelligent behaviours, behavioural processes, rational decisions, language semantics, visual semantics, causal inferences, and generic systems.

Almost all these complex objects with $\mathbb{H}$ are the targets objects and typical problems in contemporary disciplines such as cognitive informatics, cognitive computing, abstract intelligence, artificial intelligence, computational intelligence, semantic computing, software science, knowledge science, system science, and computing with words.

THE STRUCTURE OF CONCEPT ALGEBRA

Broadly speaking, a *concept* is the fundamental unit of human knowledge and reasoning. In cognitive informatics, a *concept* is a basic cognitive unit to identify and model a concrete entity in the external world or an abstract object in the perceived world. Its identification is possible only within a semantic framework defined as follows. Concepts are identified as the basic unit of both knowledge and reasoning in cognitive informatics, logic, linguistics, psychology, software engineering, knowledge engineering, artificial intelligence, and computational intelligence.

Formal treatments of concepts by rigorous mathematical models are at the centre of theories

for knowledge representation and manipulation. A concept in linguistics is a noun or noun-phrase that serves as the subject or object of a to-be statement, which can be extended to verbs or verb-phrases for denoting a behaviour. Concepts in denotational mathematics are an abstract structure that carries certain meaning in almost all cognitive processes such as thinking, knowledge representation, learning, and reasoning.

Let $\mathcal{O}$ be a finite and non-empty set of concrete or abstract *objects*, and $\mathcal{A}$ a finite and non-empty set of general *attributes*. Then, a *semantic framework* $\mathcal{F}_{sem}$, is a denotational algebraic system

$\mathcal{F}_{sem} \stackrel{def}{=} (\mathcal{O}, \mathcal{A}, \mathcal{R}_{sem})$, where $\mathcal{R}_{sem}$ is a finite and non-empty set of binary univocal or plurivocal relations, meaning-related, whose domains and codomains are $\mathcal{O}$ and/or $\mathcal{A}$, that is to say, each element $R \in \mathcal{R}_{sem}$ is such that $R \subseteq \mathcal{O} \times \mathcal{A}$ or $R \subseteq \mathcal{A} \times \mathcal{O}$.

So, for example, a binary relation of the type $\mathcal{O} \rightarrow \mathcal{A}$, assigns possible meanings, through attributes of $\mathcal{A}$, to objects of $\mathcal{O}$, while a binary relation of the type $\mathcal{A} \rightarrow \mathcal{O}$, identifies the set of objects of $\mathcal{O}$ having certain attributes belonging to $\mathcal{A}$; likewise, relations of the type $\mathcal{A} \rightarrow \mathcal{A}$, $\mathcal{O} \rightarrow \mathcal{O}$, identify respectively attributes and objects whose meanings are somehow related of each other.

An abstract concept $C_{\mathcal{F}_{sem}}$ in the semantic framework $\mathcal{F}_{sem} = (\mathcal{O}, \mathcal{A}, \mathcal{R}_{sem})$, is a denotational algebraic system of the type $C_{\mathcal{F}_{sem}} \stackrel{def}{=} (\mathcal{O}, A, R^c, R^i, R^o)$, where $\mathcal{O} \in \mathcal{P}(\mathcal{O})$ ($\stackrel{def}{=} \text{power set of } \mathcal{O}$), $A \in \mathcal{P}(\mathcal{A})$ ($\stackrel{def}{=} \text{power set of } \mathcal{A}$), and $R^c \in \mathcal{P}(\mathcal{R}_{sem})$ are finite and non-empty sets respectively of internal objects, internal attributes and internal relations of the abstract concept $C_{\mathcal{F}_{sem}}$ with respect to $\mathcal{F}_{sem}$, while $R^i \subseteq A' \times A$ and $R^o \subseteq A \times A''$, where $A', A'' \in \mathcal{P}(\mathcal{A})$ are assigned finite and non-empty sets of external attributes such that⁴

$A \cap A' = A \cap A'' = \phi$, are respectively input (A') and output (A'') relations of the abstract concept $C_{\mathcal{F}_{sem}}$ with respect to $\mathcal{F}_{sem}$.

A *concept algebra* $\mathfrak{C}_{\mathcal{F}_{sem}}$ in the semantic framework $\mathcal{F}_{sem} = (\mathcal{O}, \mathcal{A}, \mathcal{R}_{sem})$, is a denotational algebraic system of the type $\mathfrak{C}_{\mathcal{F}_{sem}} \stackrel{def}{=} (\mathcal{C}_{\mathcal{F}_{sem}}, \mathfrak{D})$, where $\mathcal{C}_{\mathcal{F}_{sem}}$ is a set of abstract concepts $C_{\mathcal{F}_{sem}}$ in the semantic framework $\mathcal{F}_{sem}$, and $\mathfrak{D} \stackrel{def}{=} \{\mathcal{R}_r, \mathcal{R}_p, \mathcal{R}_c\}$ is a set of *relational* ($\mathcal{R}_r$), *reproductive* ($\mathcal{R}_p$) and *compositional* ($\mathcal{R}_c$) computational relations among abstract concepts belonging to $\mathcal{C}_{\mathcal{F}_{sem}}$.

Among other things, concept algebra provides a denotational mathematical means for algebraic manipulations of abstract concepts. Concept algebra can be used to model, specify, and manipulate generic “to be” type problems, particularly system architectures, knowledge bases, and system refinement, in cognitive informatics, knowledge science, computational intelligence, computing science, software science, and computational linguistics. Learning is an high-level cognitive process according to the so-called *Layered Reference Model of the Brain* (LRMB) in cognitive informatics.

As a core capability of the natural and machine intelligence, learning gains knowledge of something or acquires skills in some actions by updating the cognitive models in *Long-Term Memory* (LTM). According to the *Object-Attribute-Relation* (OAR) model, the results of learning can be embodied by the updating of the existing OAR in the brain. In other words, learning is a dynamic composition of the currently created sub-OAR and the existing OAR in LTM.

THE STRUCTURE OF REAL-TIME PROCESS ALGEBRA

A central task of software science is the simulation of the behaviour of an arbitrary *intelligent system*

S . The most typical feature of an arbitrary intelligent system S , we deem to be its *memory* M_S .

A *behaviour* $\mathcal{B}$ of S is then operationally ruled by M_S , through a given set of computational operations $\mathcal{O}_S$, i.e., one or several variable mathematical functions input/output-producing, which governs a certain *action* $\mathcal{A}$ of S performed into a given *environment* $\mathcal{E}$, usually a *space-time* ST , in a certain time interval $\mathcal{T}$ specifying its *lifetime*. In dependence on $\mathcal{T}$ is a *compile* time $\mathcal{T}_c$ or a *run* time $\mathcal{T}_r$, $\mathcal{B}$ is respectively classified as a *static* behaviour or as a *dynamic* behaviour.

The basic units of system behaviours can be formalized through *processes*, which are defined as follows. Let $\mathfrak{V}$ be a finite and non-empty set of *variables* (or *operands*), $\mathfrak{S}$ a finite and non-empty set of *structures*, $\mathfrak{T}$ a finite and non-empty set of *types* (or *languages*), $\mathfrak{P}$ a finite and non-empty set of *meta-processes*, and $\mathfrak{R}$ a finite and non-empty set of *relational operators* or *process relations*. In general, $\mathfrak{S} \subseteq \mathfrak{V} \times \mathfrak{V}$, $\mathfrak{R} \subseteq \mathfrak{P} \times \mathfrak{P}$.

A meta-process of $\mathfrak{P}$ is a primitive or irreducible computational operation that cannot be reduced further to individual actions or behaviours, while a process relation of $\mathfrak{R}$ is an algebraic operation or a compositional rule between two or more meta-processes which gives rise to other more complex processes. The denotational algebraic system $\mathcal{F}_{pr} \stackrel{def}{=} (\mathfrak{V}, \mathfrak{S}, \mathfrak{T}, \mathfrak{P}, \mathfrak{R})$ is said to be a *process framework*.

An *abstract process* P in the process framework $\mathcal{F}_{pr} = (\mathfrak{V}, \mathfrak{S}, \mathfrak{T}, \mathfrak{P}, \mathfrak{R})$, is given by a finite, well-defined process iteration, i.e.,

$$P \stackrel{def}{=} \odot_{i=1}^{n-1} \gamma_{ii+1}(p_i, p_{i+1}) = p_1 \circ p_2 \circ \dots \circ p_n,$$
 which is a compendious notation for the sequence

of processes $\xrightarrow{p_1} \gamma_{12} \xrightarrow{p_2} \gamma_{23} \xrightarrow{p_3} \dots \xrightarrow{p_{n-1}} \gamma_{n-1n} \xrightarrow{p_n}$, in which $p_i \in \mathfrak{P}$ for each i , and $\gamma_{ij} \in \mathfrak{R}$ for each i, j . The big operator $\odot$ denotes a finite series of repetitive functions or composition of functions, which indicates that any i th function (statement)

given in a process P , is a relational composition with all cumulated $i-1$ previous functions.

A *real-time process algebra* $\wp_{\mathcal{F}_{pr}}$ in the process framework $\mathcal{F}_{pr} = (\mathfrak{V}, \mathfrak{S}, \mathfrak{T}, \mathfrak{P}, \mathfrak{R})$, is a denotational algebraic system of the type $\wp_{\mathcal{F}_{pr}} \stackrel{def}{=} (\mathcal{T}, \mathcal{P}, \mathcal{R})$, where $\mathcal{T} \subseteq \mathfrak{T}$ is a finite and non-empty set of primitive types for modelling computational entities, $\mathcal{P} \subseteq \mathfrak{P}$ is a finite and non-empty set of meta-processes for modelling fundamental system behaviours, and $\mathcal{R} \subseteq \mathfrak{R}$ is a finite and non-empty set of relational and compositional operators acting on $\mathcal{P}$ to build up complex system behaviours. There are applications of RTPA in human and system behavioural and functional modelling.

RTPA provides a coherent notation system and a formal engineering methodology for modelling software and intelligent systems as well as human behaviours. RTPA can be used to describe both logical and physical models of systems, where logic views of the architecture of a software system and its operational platform can be described using the same set of unified mathematical notations. When the system architecture is formally modelled, the process behaviours that perform on the structural models can be rigorously specified.

THE STRUCTURE OF SYSTEM ALGEBRA

Systemic approach to science is based on the general notion of *system* which, broadly speaking, is a coherent collection of interacting entities within a stable and well-defined environment. A system may be *open* or *closed* in dependence of its interactions with the related environment Θ . For the former, typical interactions with the environment occur with a wide range of inputs and outputs.

Let $\mathfrak{C}$ be a finite and non-empty set of *components*, $\mathfrak{B}$ a finite and non-empty set of *behaviours*, and $\mathfrak{R}$ a finite and non-empty set of binary relations between $\mathfrak{C}$ and $\mathfrak{B}$. Then, the

algebraic system $\mathcal{F}_{sys} \stackrel{def}{=} (\mathfrak{C}, \mathfrak{B}, \mathfrak{R})$ is said to be a *system framework*. An *abstract system* $\mathcal{S}_{\mathcal{F}_{sys}}$ in the system framework $\mathcal{F}_{sys} = (\mathfrak{C}, \mathfrak{B}, \mathfrak{R})$, is a denotational algebraic system of the type $\mathcal{S}_{\mathcal{F}_{sys}} \stackrel{def}{=} (C, B, R^c, R^i, R^o, \odot, \sim)$, where $C \subseteq \mathfrak{C}$ is a finite and non-empty set of *internal* components, $B \subseteq \mathfrak{B}$ is a finite and non-empty set of *internal* behaviours, $R^c \subseteq \mathfrak{R}$ is a finite and non-empty set of *internal* relations, $R^i \subseteq C' \times C$ is a finite and non-empty set of *input* (C') relations, $R^o \subseteq C \times C''$ is a finite and non-empty set of *output* (C'') relations, where $C', C'' \subseteq \mathfrak{C}$ are finite and non-empty subsets of *external* components of the *environment* $\sim = \{C', C''\} \subseteq \mathcal{P}(\mathfrak{C})$ ($=$ power set of $\mathfrak{C}$) such that⁵ $C' \cap C = C'' \cap C = \emptyset$, and $\odot \subseteq \mathfrak{B}$ is a finite and non-empty set of behaviours, said to be *constraints* on C and B , which provide further information about their elements.

A *system algebra* $\mathcal{SA}_{\mathcal{F}_{sys}}$ in the system framework $\mathcal{F}_{sys}$, is a denotational algebraic system of the type $\mathcal{SA}_{\mathcal{F}_{sys}} \stackrel{def}{=} (\mathfrak{G}_{\mathcal{F}_{sys}}, \mathcal{R})$, where $\mathfrak{G}_{\mathcal{F}_{sys}}$ is a set of system algebras of the type $\mathcal{S}_{\mathcal{F}_{sys}}$, while $\mathcal{R}$ is a finite set of computational relations among elements of $\mathfrak{G}_{\mathcal{F}_{sys}}$.

System algebra is a denotational mathematics for rigorous system modelling, computing, and manipulation. System algebra models any concrete system using the general abstract system model and manipulates complex system behaviours as algebraic operations on the abstract system. System algebra provides a denotational mathematical means for algebraic manipulations of all forms of abstract systems.

System algebra can be used to model, specify, and manipulate generic “to be” and “to have” type problems, particularly system architectures, system analyses, system refinements, and system syntheses in extremely wide areas. System algebra

is not only useful for system behavioural manipulations, but also efficient in system architectural modelling and refinement. In the latter case, a system can be integrated from the bottom up by a series of compositions level-by-level in a given system hierarchy.

THE STRUCTURE OF VISUAL SEMANTIC ALGEBRA

In order to model abstract visual objects, particularly their semantic representation, composition and manipulation as symbolic semantic entities, the structure of visual semantic algebra is introduced. In this regard, the basic 2-D and 3-D geometric units, collectively known as *geons*, will be the primary and fundamental elements to build up visual semantic algebra.

Let $\mathfrak{O}$ be a finite and non-empty set of *visual objects* (or *geons*), and $\mathfrak{R}$ a finite and non-empty set of *spatial relational operations*, which formalize the basic, elementary geometric transformations. Then, the denotational algebraic system $\mathcal{F}_{vis}^{def} = (\mathfrak{O}, \mathfrak{R})$ is said to be a *visual object framework*.

Usually, $\mathfrak{R} \subseteq \mathfrak{O} \times \mathfrak{O}$, while the set of *primitive* or *irreducible visual objects* O is given by the union of the sets of 2-D shapes (H), 3-D solids (S), generic figures (F) and spatial reference limits (L), that is, $O = H \cup S \cup F \cup L$, which will be related among them through algebraic operations whose set $R \subseteq \mathfrak{R}$ comprehends relational and behavioural computational operators.

The denotational algebraic system $\mathcal{VA}_{\mathcal{F}_{vis}}^{def} = (O, R)$ is said to be a *visual semantic algebra*.

The physical space is used to be formally modelled by the Euclidean space that is a collection of all abstract points in three coordinates. Therefore, the spatial properties of concrete and abstract objects, shapes, and their interrelations can be described by Euclidean plane and solid geometry.

However, it is discovered that the brain does not process visual objects and patterns as bit maps as a camera rather than representing them as abstract visual semantics, because the latter approach is more efficient in visual information processing.

In order to efficiently model the abstract visual objects, particularly their semantic representations, compositions, and manipulations, a new structure of denotational mathematics known as visual semantic algebra is introduced in this section for expressing the semantics of visual objects and patterns in cognitive computing.

THE STRUCTURE OF GRANULAR ALGEBRA

A *computing granule* is the basic mathematical structure of a *granular system*, with a stable topological setting and bearing, at least, a unit of computational capability or behaviour. If $\mathfrak{E}$ is a finite and non-empty set of *granules*, $\mathfrak{R}$ a finite and non-empty set of *relations* on $\mathfrak{E}$, and $\mathfrak{C}$ a finite and non-empty set of *constraints* on $\mathfrak{E}$ and $\mathfrak{R}$, then the denotational algebraic system

$\mathcal{F}_{gr}^{def} = (\mathfrak{E}, \mathfrak{R}, \mathfrak{C})$ is said to be a *granular framework*.

An *abstract granule* $\mathcal{G}_{\mathcal{F}_{gr}}$ in the granular framework $\mathcal{F}_{gr} = (\mathfrak{E}, \mathfrak{R}, \mathfrak{C})$, is a denotational algebraic system of the type $\mathcal{G}_{\mathcal{F}_{gr}}^{def} = (G, B, R^c, R^i, R^o, \odot, \sim)$, where $G \subseteq \mathcal{P}(\mathfrak{E})$ is a finite and non-empty set of *cells* of granules, $B \subseteq \mathfrak{R}$ is a finite and non-empty set of *behaviours* of G , $R^c \subseteq \mathfrak{R}$ is a finite and non-empty set of *internal relations*, $R^i \subseteq G' \times G$ is a finite and non-empty set of *input* (G') relations, $R^o \subseteq G \times G''$ is a finite and non-empty set of *output* (G'') relations, $\odot \subseteq \mathfrak{C}$ is a finite and non-empty set of *constraints* on G and B , and $\sim = \{G', G''\} \subseteq \mathcal{P}(\mathfrak{E})$ is the *environment* of $\mathcal{G}_{\mathcal{F}_{gr}}$ made by the *external cells* G', G'' , outside G , such that⁶ $G' \cap G = G'' \cap G = \phi$.

A granular algebra $\mathcal{GA}_{\mathcal{F}_{gr}}$ in the granular framework $\mathcal{F}_{gr} = (\mathfrak{C}, \mathfrak{R}, \mathfrak{E})$, is a denotational algebraic structure of the type $\mathcal{GA}_{\mathcal{F}_{gr}} \stackrel{def}{=} (\mathcal{G}, \mathcal{R})$, where $\mathcal{G}$ is a finite and non-empty set of abstract granules $\mathcal{G}_{\mathcal{F}_{gr}}$ in the granular framework $\mathcal{F}_{gr}$, and $\mathcal{R}$ is a finite and non-empty set of computational relations among elements of $\mathcal{G}$.

Granular algebra is a denotational mathematical structure for modelling granular systems and granular computing. The term granule is originated from Latin granum, i.e., grain, to denote a small compact particle in physics and in the natural world. However, the taxonomy of granules in computing can be classified into data granule, information granule, concept granule, computing granule, cognitive granule, and system granule.

A computing granule, shortly a granule, is a basic mathematical structure that possesses a stable topology and at least a unit of computational capability or behaviour. Granular computing is a new computational methodology that models and implements computational structures and functions by a granular system, where each granule in the system carries out a predefined function or behaviour by interacting to other granules in the system.

THE STRUCTURE OF INFERENCE ALGEBRA

Inferences are the basic elements of formal reasoning. *Inference algebra* formalizes usual, everyday and empirical cause-effect type reasoning processes in a rigorous fashion, trying to identify and reveal the possible causations in a thread of thought, so allowing their computational implementations in the cognitive informatics context.

Let $\mathfrak{S}$ be a finite and non-empty set of *states* or *facts*, given by the union of the sets of *causes* $\mathfrak{C}$ and *effects* $\mathfrak{E}$, and $\mathfrak{R}$ a finite and non-empty set of relations among causes and effects, i.e., $\mathfrak{R} \subseteq \mathfrak{C} \times \mathfrak{E}$, said to be *causations*. Then, the

denotational algebraic system $\mathcal{F}_{inf} \stackrel{def}{=} (\mathfrak{C}, \mathfrak{E}, \mathfrak{R})$ is said to be an *inference framework*.

An *abstract causation* ξ in the inference framework $\mathcal{F}_{inf} = (\mathfrak{C}, \mathfrak{E}, \mathfrak{R})$, is a functional relation $\xi \in \mathfrak{R}$ of the type $f_\xi: C \rightarrow E$ which maps a non-empty set of causes $C \subseteq \mathfrak{C}$ onto a set of effects $E \subseteq \mathfrak{E}$. If $\mathfrak{Z}_{\mathcal{F}_{inf}} \subseteq \mathfrak{R}$ is the category of abstract causations in the inference framework $\mathcal{F}_{inf}$, then $\mathfrak{Z}_{\mathcal{F}_{inf}}$ consists in four main types of formal causations in dependence on these are formally considered as functions in Boolean or numerical variables.

A *formal inference* κ in the inference framework $\mathcal{F}_{inf}$, is a formal reasoning process which identifies a causation $\xi \in \mathfrak{Z}_{\mathcal{F}_{inf}}$, say $f_\xi = \vdash$, between the elements of a certain pair (C, E) of non-empty sets of causes $C \subseteq \mathfrak{C}$ and effects $E \subseteq \mathfrak{E}$, that is to say, $\kappa = C \vdash E = f_\xi(C)$.

An *inference algebra* $\mathcal{IA}_{\mathcal{F}_{inf}}$ in the inference framework $\mathcal{F}_{inf}$, is a denotational algebraic system $\mathcal{IA}_{\mathcal{F}_{inf}} \stackrel{def}{=} (\mathfrak{Z}, \mathfrak{R})$, where $\mathfrak{Z}$ is a finite and non-empty set of formal inferences κ , and $\mathfrak{R}$ is a finite and non-empty set of computational relations between elements of $\mathfrak{Z}$.

Inference algebra is a denotational mathematics for cognitive computing and machine reasoning. Inference as the basic mechanism of thought is one of the gifted abilities of human beings, which is a cognitive process that creates rational causations between a pair of cause and effect based on empirical arguments, formal reasoning, and/or statistical norms. Inference algebra introduces a calculus of discrete causal differential and formal models of causations, based on them nine algebraic inference operators of inference algebra are created for manipulating the formal causations.

Inference algebra elicits and formalizes the common and empirical reasoning processes in a rigorous form, which enable artificial intelligence and computational intelligent systems to mimic

human inference abilities in cognitive computing. Inference algebra is one of the basic studies towards the next generation of intelligent computers known as cognitive computers. A wide range of applications of inference algebra are identified and demonstrated in cognitive informatics and computational intelligence towards novel theories and technologies for machine-enabled inferences and reasoning.

FUTURE RESEARCH DIRECTIONS

Among the typical paradigms of denotational mathematics, above all concept algebra has been designed for knowledge processing in cognitive computing, computational linguistics, and computational intelligence, which models concrete knowledge as abstract concepts and semantic relations, and manipulates complex knowledge and semantics as algebraic operations on the abstract concepts.

Real-Time process algebra (RTPA) has been designed for manipulating computational structures and behaviours, which models concrete data objects as structure models (SMs), represents system behaviours as process models (PMs), and manipulates complex behavioural processes as algebraic operations on the abstract SMs and PMs. System algebra (SA) has been designed for rigorous system manipulations, which represents real-world systems using the universal abstract system model and manipulates complex system behaviours as algebraic operations on the abstract systems.

Visual Semantic Algebra (VSA) has been designed for geometric analyses and compositions of visual patterns, which models visual objects and patterns as abstract and symbolic semantic entities and manipulates complex visual semantics as algebraic operations on the abstract semantic objects. Granular algebra (GA) has been designed for granular computing, which models concrete granules as an abstract mathematical structure

and manipulates complex granular behaviours as algebraic operations on the abstract granules.

Inference algebra (IA) has been designed for cognitive computing and machinable thought, which models human and machine inferences as abstract causations and manipulates complex inference processes as algebraic operations on the abstract causations. Based on these fundamental researches, denotational mathematics, as a metamethodology, has found a wide range of applications in formal inferences, knowledge manipulations, cognitive learning, as well as complex system modelling.

CONCLUSION

In the present contribution, we have outlined, in a very brief but rigorous manner, the basic formal structures of denotational mathematics, according to Y. Wang, from an elementary algebraic standpoint, making use of naïve set theory to be clearer in the explanation of their basic mathematical essence.

We have left out to quote the sources and motivations for these new algebraic structures, mainly coming from computer sciences, as well as their possible applications, referring to the original Wang's papers to this end, as reported, for example, in (Wang, 2012b).

In another place, instead, we will give a more exhaustive and complete formal exposition of the same above mentioned formal structures, but conducted within the wider and more general framework of model theory. The real-world expressional needs for denotational mathematics are such as abstraction of system structures and system behaviours, knowledge representation and manipulations, intelligence generation, effective complexity handling, rigorous system modelling, and expressive system denotation. These practical demands for denotational mathematics are driven by applications in the emerging fields of cognitive informatics, intelligence science, knowledge sci-

ence, brain science, computational intelligence, software science, system science, and cognitive computers.

The extension of conventional algebra onto more complicated mathematical objects beyond pure numbers leads to the contemporary denotational mathematics, which is applied to denote complex behaviours and long chains of inference processes of humans and intelligent systems. It is recognized that humans are not thinking and reasoning at the binary level in $\mathbb{B}$ or $\mathbb{R}$. Denotational mathematics extends the mathematical means for rigorous inference and modelling to a higher level, $\mathbb{H}$, closer to that of humans. Six paradigms of denotational mathematics such as concept algebra, RTPA, system algebra, VSA, granular algebra, and inference algebra will be described in the following sections.

A set of novel operators for each paradigm of denotational mathematics will be elaborated. Typical applications of denotational mathematics will be demonstrated in each section, which show how denotational mathematics may greatly improve the expressive power and efficiency in complex system modelling and intelligent behaviour manipulations. A general finding in computer science, system science, and denotational mathematics is that any complex system may be modelled by the interactions between its structures and functions (behaviours).

The six paradigms of denotational mathematics as presented in the following sections indicate that, although the general model of denotational mathematics is unique, the specific forms of each denotational mathematics and the operators on its structures vary due to the differences of the hyperstructural models of specific mathematical objects such as the abstract concept, system, granule, and causation. This is perfectly in line with the basic system principle that the structure determines or affects the behaviours and mathematical operations on it.

Quantum Computing and Quantum Communication

T

Göran Pulkkis*Arcada University of Applied Sciences, Finland***Kaj J. Grahn***Arcada University of Applied Sciences, Finland*

INTRODUCTION

Quantum computing and quantum communication are based on quantum physics. Information is represented by quantum states defined by energy levels of molecules, atoms, and photons. Quantum information technology includes quantum computers, other quantum information processing devices, quantum programming methodologies, and quantum communication applications such as quantum key distribution systems and quantum signatures. Error correction is a necessary quantum information technology property because of high error vulnerability caused by quantum physics characteristics. This article presents state-of-the-art and future perspectives of quantum computing and communication.

BACKGROUND

Feynman's (1982) observation, that a classical computer cannot efficiently simulate the stochastic parallelism of quantum states, started research on using quantum mechanical effects for efficient information processing. Operating principles and implementation possibilities of quantum computing were outlined in Oxford University (Deutsch, 1985).

Bennett and Brassard (1984) proposed a quantum protocol, BB84, for perfectly secret information transfer. Efficient quantum algorithms, for example integer factorization (Shor, 1994) and

unsorted search (Grover, 1996), were proposed. BB84 has been used for distribution of symmetric encryption/decryption keys (Quantum Key Distribution, QKD) in research networks (Elliot, Pearson, & Troxel, 2004; Quellette, 2004; Poppe, Momtchil, & Maurhart, 2008). Commercial QKD technology has been available over 10 years. Quantum digital signatures have been proposed and experimentally verified (Gottesman & Chuang, 2001; Lu & Feng, 2005; Clarke et al., 2012).

Small scale quantum circuit based computers have been built and successfully tested in research laboratories (Vandersypen et al., 2001; Monz et al., 2011). Since 2011 large scale commercial adiabatic quantum computers (Das & Chakrabarti, 2008) are available.

Achievements in quantum computing and quantum communication from 1970 till October 2015 are listed in (Timeline, 2015). Universities engaged in research and education on this topic are for example (qis.mit.edu, 2013; ...from Quantum, 2011; mathQI, 2015; Quantum, 2015a; Quantum, 2015b)

INFORMATION REPRESENTATION WITH QUANTUM STATES

Two quantum states, for which a state transition exists, can represent a bit called a quantum bit or qubit, if the energy level of both states is measurable. However, quantum states are probabilistic. A measured energy level is one of several possi-

bilities. Each possible outcome has a probability. The sum of all possible outcome probabilities is of course 1.

The *No Cloning* qubit property is the impossibility to clone an unknown quantum state. However, *Teleportation*, which changes the original qubit state, can transfer also an unknown quantum state.

Mathematical Treatment of Qubits

A qubit representation is a 2-dimensional vector. The orthogonal base vectors $(1,0)^T, (0,1)^T$ in *Dirac notation* $|0\rangle, |1\rangle$ represent binary values 0,1.

A qubit is a concurrent superposition of $|0\rangle, |1\rangle$. A measurement outcome is $|0\rangle$ or $|1\rangle$. In a qubit

$$|\psi\rangle = a \cdot |0\rangle + b \cdot |1\rangle. \quad (1)$$

a, b are complex numbers and

$$\langle \psi | \psi \rangle = (a^*, b^*) \cdot (a, b)^T = a^* \cdot a + b^* \cdot b = |a|^2 + |b|^2 = 1. \quad (2)$$

$\{a^*, b^*\}$ are complex conjugates of $\{a, b\}$. $\{|a|^2, |b|^2\}$ are measurement probabilities of $|0\rangle, |1\rangle$.

Multiple Qubits

A 2 *qubit* quantum state is a 2^2 component column vector. For

$$|\psi_1\rangle = a \cdot |0\rangle + b \cdot |1\rangle, |\psi_2\rangle = c \cdot |0\rangle + d \cdot |1\rangle \quad (3)$$

the state is

$$|\psi_1 \psi_2\rangle = |\psi_1\rangle \otimes |\psi_2\rangle = a \cdot c \cdot |00\rangle + a \cdot d \cdot |01\rangle + b \cdot c \cdot |10\rangle + b \cdot d \cdot |11\rangle. \quad (4)$$

$\otimes$ is the *tensor product*. $|00\rangle = |0\rangle \otimes |0\rangle = (1, 0, 0, 0)^T$, $|01\rangle = |0\rangle \otimes |1\rangle = (0, 1, 0, 0)^T$, $|10\rangle = |1\rangle \otimes |0\rangle = (0, 0, 1, 0)^T$, and $|11\rangle = |1\rangle \otimes |1\rangle = (0, 0, 0, 1)^T$ are the *base vectors*.

A N *qubit* quantum state $|\psi_1 \psi_2 \dots \psi_N\rangle$ is a superposition of 2^N base vectors. For a 3 qubit state $|\psi_1 \psi_2 \psi_3\rangle$ the base vectors are $\{|000\rangle, |001\rangle, |010\rangle, |011\rangle, |100\rangle, |101\rangle, |110\rangle, |111\rangle\}$, where $|001\rangle = |0\rangle \otimes |0\rangle \otimes |1\rangle = (0, 1, 0, 0, 0, 0, 0, 0)^T$, etc.

The state $|\psi_1 \psi_2 \dots \psi_N\rangle$ is *entangled* if no $|\psi_1\rangle, |\psi_2\rangle, \dots, |\psi_N\rangle$ exist for which $|\psi_1 \psi_2 \dots \psi_N\rangle = |\psi_1\rangle \otimes |\psi_2\rangle \otimes \dots \otimes |\psi_N\rangle$.

Example: $(1/\sqrt{2}) \cdot (|00\rangle + |11\rangle)$ is entangled.

Proof: $(a \cdot |0\rangle + b \cdot |1\rangle) \otimes (c \cdot |0\rangle + d \cdot |1\rangle) = a \cdot c \cdot |00\rangle + a \cdot d \cdot |01\rangle + b \cdot c \cdot |10\rangle + b \cdot d \cdot |11\rangle \neq (1/\sqrt{2}) \cdot (|00\rangle + |11\rangle)$, since one of $\{a, d\}$ must be 0.

Physical Implementation of Qubits

Qubits have been implemented by photon states, ion traps, cavity quantum electrodynamics (QED), nuclear magnetic resonance (NMR), quantum dots, superconducting circuits, and in silicon (Nielsen & Chuang, 2002; Devoret & Schoelkopf, 2013; Veldhorst et al., 2015).

A physical qubit property is decoherence time, during which a qubit state is maintained before collaps caused by interaction with the physical environment.

A qubit implementation in quantum communication is a photon *polarization state* consisting of all propagation planes of the electromagnetic wave of the photon. A random polarization is a superposition of an orthogonal state pair. Orthogonal state pair examples:

- Horizontal and vertical polarization.
- $+45^\circ$ and -45° diagonal polarization.

A photon polarization state is thus a qubit

$$|\psi\rangle = a \cdot |horis\rangle + b \cdot |vert\rangle = c \cdot | +45^\circ \rangle + d \cdot | -45^\circ \rangle \quad (5)$$

a, b, c, d are complex numbers and $|a|^2 + |b|^2 = |c|^2 + |d|^2 = 1$. One state in a chosen pair must be interpreted as $|0\rangle$, the other as $|1\rangle$. Pho-

ton polarization is measured with a filter. After measurement, only the component allowed by the filter proceeds.

The No Cloning qubit property prevents copying unknown polarization which, however, can be teleported between photons.

QUANTUM COMPUTING

This chapter outlines quantum computation models, quantum algorithms, quantum programming, and quantum computation realizations.

Quantum Computation Models

Proposed models:

- **Quantum Circuit:** Computations are sequences of quantum gate operations, which are reversible transformations on multiple bit quantum registers.
- **Adiabatic Quantum Computer:** Computing by quantum annealing (Das & Chakrabarti, 2008).
- **One-Way Quantum Computer:** An entangled resource state is prepared and thereafter qubits are measured (Raussendorf & Briegel, 2001).
- **Topological Quantum Computer:** Computation is decomposed into braiding of anyons in a 2D lattice (Sarma, Freedman, & Nayak, 2006).

This subchapter presents the quantum circuit and the adiabatic quantum computation models, which are shown to be equivalent (Aharonov et al., 2004).

Quantum Gates and Circuits

Quantum gates change qubit states. Single qubit gates:

- Identity I , $I \cdot |\psi\rangle = |\psi\rangle$
- Negation X (Pauli x), $X \cdot |0\rangle = |1\rangle$, $X \cdot |1\rangle = |0\rangle$
- Phase Shift Z (Pauli z), $Z \cdot |0\rangle = |0\rangle$, $Z \cdot |1\rangle = (-1) \cdot |1\rangle$
- Hadamard H , $H \cdot |0\rangle = 2^{-1/2} \cdot (|0\rangle + |1\rangle)$, $H \cdot |1\rangle = 2^{-1/2} \cdot (|0\rangle - |1\rangle)$

2 qubit gates:

- Identity I , $I \cdot |\psi_1 \psi_2\rangle = |\psi_1 \psi_2\rangle$
- Controlled-NOT C_{not} , $C_{not} \cdot |0\psi\rangle = |0\psi\rangle$, $C_{not} \cdot |1\psi\rangle = |1\rangle \otimes X \cdot |\psi\rangle$

$N \geq 2$ qubit gates are $2^N \times 2^N$ matrices G and $G \cdot G^* = I$. G^* is the complex conjugate matrix of G .

Quantum circuit: an interconnection of quantum gates. Figure 1: a teleportation circuit. The upper qubit is the control in both C_{not} gates. $m1, m2$ are measured qubit values. $X^{m2} = I, X$ for $m2 = 0, 1$. $Z^{m1} = I, Z$ for $m1 = 0, 1$. No Cloning occurs, since measurement $m1$ changes $|\psi\rangle$.

Figure 1. Quantum circuit teleporting the unknown qubit state $|\psi\rangle = a \cdot |0\rangle + b \cdot |1\rangle$ to $|\theta\rangle$

Adiabatic Quantum Computation (AQC)

AQC is based on Schrödinger equation

$$i\hbar \frac{d|\Psi(t)\rangle}{dt} = H|\Psi(t)\rangle \quad (6)$$

and the adiabatic theorem for calculations. i is the imaginary unit, $\hbar$ is the reduced Planck constant, $|\Psi(t)\rangle$ is the quantum system state at time t , and H is the Hamiltonian operator characterizing the total quantum system energy. In an n qubit system H is a $2^n \times 2^n$ hermitian matrix. The eigenvalues $\{E_i\}$, $i=0,1,2,\dots,n-1$ of H represent energies. Eigenvector(s) corresponding to the lowest eigenvalue represent *ground state(s)*.

In an n qubit system, the unknown ground state a Hamiltonian H_{final} represents a problem solution. The system is initialized to the ground state of a chosen Hamiltonian H_{init} , which is adiabatically evolved to H_{final} by applying

$$H(t) = A(t) \cdot H_{\text{init}} + B(t) \cdot H_{\text{final}} \quad (7)$$

during the time t , $0 \leq t \leq T$. The adiabatic theorem: the system remains in the ground state, if T is sufficiently long and the difference between the two smallest eigenvalues of $H(t/T)$ is strictly >0 when $0 \leq t \leq T$. The terminal system state represents the problem solution. (Farhi, Goldstone, Gutmann, & Sipser, 2000)

Quantum Algorithms

A quantum circuit computation algorithm: qubit state changes in quantum gates and qubit state measurements. Any classical algorithm can be realized in a quantum circuit based computer. Some quantum algorithms have lower computational complexity than corresponding classical algorithms. Best known classical algorithm to disclose a private RSA key has superpolynomial complexity. Shor's factorization quantum algo-

rithm (Shor, 1994) discloses a n bit private RSA key with polynomial (cubic) complexity in a $1.5 \times n$ qubit quantum computer. Best classical algorithms for unsorted database search and solving linear equation sets have linear complexity. In a quantum computer with sufficiently many qubits, unsorted size n search has $O(\sqrt{n})$ complexity (Grover, 1996) and solving linear equation sets has logarithmic complexity (Cai et al., 2013).

Quantum annealing is an AQC algorithm for minimizing a given object function represented by a Hamiltonian, whose ground state represents the minimum. Such object function:

$$E(\mathbf{s}) = -\sum_{i=1}^N h_i \cdot s_i + \sum_{i<j} K_{ij} \cdot s_i \cdot s_j \quad (8)$$

Binary values in $\mathbf{s} = [s_1, s_2, \dots, s_N]$ should be chosen to minimize $E(\mathbf{s})$. h_i , K_{ij} are dimensionless real numbers. No classical algorithm with polynomial complexity is known for finding the minimal of 2^N possible combinations. Faster minimization is expected from quantum annealing. The minimum is the ground state of the Hamiltonian

$$H_F = -\sum_{i=1}^N h_i \cdot \sigma_z^i + \sum_{i<j} K_{ij} \cdot \sigma_z^i \cdot \sigma_z^j \quad (9)$$

in a N qubit system, where σ_z^i , σ_z^j are Pauli z matrices $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ applied to qubits i, j . To find the ground state of H_F , the Hamiltonian

$$H(t) = A(t) \cdot H_I + B(t) \cdot H_F \quad (10)$$

is adiabatically evolved from $t=0$ to T for $A(0)/B(0) \gg 1$, $A(T)/B(T) \ll 1$. The Hamiltonian

$$H_I = -\sum_{i=1}^N \sigma_x^i \quad (11)$$

with $\sigma_x^i = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ applied to qubits i is in ground

state (all qubits in state $\frac{1}{\sqrt{2}} \cdot (|0\rangle + |1\rangle)$). The functions $A(t)$, $B(t)$ must guarantee adiabatic evolution from a state very close to the ground state of H_1 to a state very close to the ground state of H_F . (Harris et al., 2009)

Quantum Programming

Several imperative and functional programming languages, usually based on the Quantum Random Access Machine where a classical device controls quantum device computations, and also some different approaches have been proposed for quantum circuit based computers (Sofge, 2008; Miszczak, 2011).

Among the first imperative languages is QCL (Quantum Computing Language) with a syntax resembling C language: The basic data type *qreg* (quantum register) defines qubit arrays. The standard library provides quantum gate operators. The *measure* statement measures qubit states. Higher abstraction level algorithms are defined like C language functions. Other imperative languages are LanQ resembling QCL and Q (Bettelli, Calarco, & Serafini, 2003) based on C++. (Miszczak, 2011)

Lambda calculus and Haskell based functional quantum programming languages have been proposed. The first proposal, lambda-q calculus (Maymin, 1997) which expresses any quantum algorithm and efficiently solves problems with NP-hard complexity, is unfortunately

more expressive than is possible to realize as a physical quantum computer. Another quantum lambda calculus proposal is defined for quantum computations with no measurements (van Tonder, 2004). Altenkirch and Grattage (2005) propose a Haskell-like quantum language, QML, expressing both classical and quantum control and data. Quipper (Green, Lumsdaine, Ross, Selinger, & Valiron, 2013) is a recent embedded functional language providing Haskell libraries for quantum programs. An introduction to AQC programming is published in (Quantum, 2014).

Physical Realization of Quantum Computers

Properties restricting quantum circuit computation realizations (see Table 1):

- **Quantum Operation Time:** Qubit state change time in a basic quantum gate.
- **Decoherence Time**
- **Scalability:** Maximal qubit set in a quantum circuit.

The maximal number of quantum program operations is (decoherence time)/(quantum operation time).

Currently only small scale quantum circuit computation realizations exist. A basic building block of a quantum computer, a two qubit quantum gate, has been implemented in silicon (Veldhorst et al., 2015). Shor's quantum factorization has been executed in a 7 qubit NMR implemented

Table 1. Quantum circuit implementations properties

Technology	Quantum Operation Time	Decoherence Time	# Quantum Operations	Scalability (# Qubits)
Ion traps	10^{-7} s	10^{-1} s	10^6	50
Cavity QED	10^{-14} s	10^{-5} s	10^9	2-5
NMR	10^{-3} s	10^4 s	10^7	10-50
Quantum Dots	10^{-9} s	10^{-6} s	10^3	1000

Source: Brown, 2001

computer (Vandersypen et al., 2001). Monz et al., (2011) describe an implemented 14 qubit register.

AQC technology is magnetically coupled Josephson junction rf-SQUID (Radio Frequency Superconducting Quantum Interference Device) flux qubits (Devoret & Schoelkopf, 2013; Harris et al., 2009). Boixo et al. (2013) report experimental quantum annealing with 108 qubits in a 128 qubit adiabatic quantum computer. A 512 qubit adiabatic quantum computer has been delivered for artificial intelligence research (Jones, 2013). Also a 1000 qubit adiabatic quantum computer, D-Wave 2X (D-Wave, 2015), is available.

QUANTUM COMMUNICATION

Quantum communication is qubit transfer and use of entanglement and teleportation to transfer qubit states between physical locations.

Qubit transfer is photon transfer, for example polarized photons, in optical fibers or along free sight paths. Current transmission range is limited by photon state decoherence to about 300 km in optical fibers (Korzh et al., 2015) and about 150 km in free sight atmosphere paths (Schmitt-Manderbach et al., 2007). The range in free sight space is considerably longer because of negligible decoherence. Secure quantum code transmission between two ground stations via satellite has been demonstrated (Physicists, 2013).

Current quantum communication applications are Quantum Key Distribution (QKD), Quantum Key Agreement, Quantum Secret Sharing (QSS), and Quantum Signatures.

Quantum Repeaters

Quantum networks over long distances are confronted with loss and operation errors, which heralded entanglement generation, purification, and deterministic quantum error correction can suppress. Used correction methods classify quantum repeaters into three generations (Munro, 2015). The first generation uses entanglement generation

and purification. Communication rate overhead is reduced from exponential to polynomial scaling with distance. The second generation replaces entanglement purification with quantum error correction, which further reduces communication rate overhead from polynomial to poly-logarithmical scaling with distance. A third generation will eliminate two-way communication with both loss and operation error correction. Then only local quantum gate speed limits communication rate.

Current optical communication technology transfers polarized photons with reasonable error rates up to about 70...100 km (Stucki, Gisin, Guinnard, Ribordy, & Zbinden, 2002; MagiQ, 2007). In long-distance quantum communication, quantum repeaters are needed on the network's physical layer. Repeaters combine entanglement swapping and quantum memories. Transmission distance is divided into segments, entanglement is distributed independently within each segment, and entanglement swapping extends entanglement distance. Segments are mutually independent. Entanglement distribution is heralded, i.e. a signal indicates successful entanglement. Entanglement is stored in quantum memories for avoiding concurrent entanglement within each segment. (de Riedmatten, 2015)

Research efforts to implement quantum repeaters are reported in (Curcic et al., 2004; QuReP, 2014).

Quantum Key Distribution (QKD)

This subchapter surveys QKD protocols and their integration in the TCP/IP network protocol stack, presents current QKD technology and applications, and describes security threats.

QKD Protocols

BB84 (Bennet & Brassard, 1984):

1. Alice sends over an optical channel to Bob a sequence of photons randomly polarized to a state in $\{|horis\rangle, |vert\rangle, |+45^\circ\rangle, |-45^\circ\rangle\}$.

Bob guesses the polarization base (horizontal/vertical or diagonal) for each photon and measures polarization.

2. Bob sends over a classical channel the guess sequence to Alice.
3. Alice replies about guess correctness.

Bob's measurements for correct guesses represent a shared secret key. See Figure 2.

If eavesdropper Eve measures photon polarization in Alice's sequence in a guessed base and forwards measured photons to Bob, then a random choice of $|0\rangle$, $|1\rangle$ is forwarded for each incorrect guess. Thus successful key creation proves absence of eavesdropping (Yanofsky & Mannucci, 2008).

BB84 is actually a "Sifting Phase" creating raw keys excluding not received photons. In a practical BB84 the shared secret contains the raw key bits remaining after "Key Distillation" including "Error Correction" to remove bits different in both raw keys and "Privacy Amplification" to drop correct bits known by a possible eavesdropper. (Elliott et al., 2003)

BB84 is a 4-state protocol as it uses four different polarization states. However, a perfectly secret QKD protocol needs only 2 non-orthogonal polarization states (Yanofsky & Mannucci, 2008). Also perfectly secret 6-state protocols have been proposed and analysed (Bruss, 1998). EPR, proposed by Einstein, Podolsk, and Rosen, is a completely different QKD protocol type based on Bell's inequality (Yanofsky & Mannucci, 2008).

QKD Based Session Keys

Elliott & al. (2003) describe QKD integration in IPSec. QKD integration in TLS/SSL requires new cipher suites defining key exchange. New ServerKeyExchange and ClientKeyExchange messages are needed.

Attacks Against QKD

Practical QKD security depends on environment noise, imperfect photon detection, and light sources properties. Some attacks are possible in ideal environments with single photon generators and 100% efficient detectors (Aggarwal, Sharma, & Gupta, 2011), while others stem from unsecure implementations (Gisin, Ribordy, Tittel, & Zbinden, 2002). Khan and Xu (2011) divide QKD communication into secret key generation, secret key storage and management, and encryption and transmission. Attack types are physical, quantum, and classical.

Quantum attacks on QKD are intercept-resend, Trojan horse, and photon number splitting (PNS) (Kahn & Xu, 2011). In *intercept-resend*, Eve guesses polarization base, measures the quantum states sent by Alice, and sends replacement states to Bob. In a *Trojan horse* attack, Eve occupies a part of the quantum channel (i.e. the spatial, temporal, and frequency modes) to probe Alice's apparatus. An auxiliary source is used and a detector analyses the backscattered signal. If Alice

Figure 2. The BB84 QKD protocol

transmits a multiple photon laser pulse, then Eve could split off photons with *PNS*. A QKD protocol, *SARG04*, using the same polarization states as BB84 with a different information encoding is less vulnerable to PNS than BB84 (Scarani, Acín, Ribordy, & Gisin, 2004).

Optical loophole attacks are strong light pulses (Bethune & Risk, 2000), high-power destruction of optical components, utilization of light emission from avalanche photodiodes, and faked states.

QKD Technology and Applications

A QKD channel is a free sight path or an optical fiber. Free sight transmission is faster. In free sight atmosphere paths distances exceed 140 km, but exchange rate is only 12 bit/s (Schmitt-Manderbach et al., 2007). Current QKD systems exchange 1 Mbit/s in 20 km fiber and 10 kbit/s when distance > 100 km (Dixon, Yuan, Dynes, Sharpe, & Shields, 2008). Modest exchange rates depend on limited single photon detection rate.

The first commercial quantum cryptography products, i.e. single photon detectors and random number generators, appeared in 2002. Encoding used photon phase.

The Swiss company ID Quantique offers for the QKD protocols BB84 and SARG04

- A QKD research platform (Clavis, 2014)
- A server combining QKD with AES (Advanced Encryption Standard), securely bridging two Fast Ethernet networks, and supporting refresh rates 1 key/minute for up to 12 encryptors and 100 km transmission distance in optical fibre (Cerberis, 2012).

QPN™ Security Gateway (MagiQ, 2007) available from the US company MagiQ Technologies, Inc. adds VPN security layers and classical data encryption to QKD. BB84, IPSec, and 256 bit AES are implemented. A refresh rate up to 100 keys/second, a transmission distance of 100 km,

and full-duplex 10/100 Ethernet ports are supported. Available is also a single photon BB84 based system (Q-BOX, 2003) for QKD research.

A QKD module with key transfer 10 kbit/s for 20 km and 100 bit/s for 80 km is available for QKD research from the French company SecCureNet (Cygnus, 2013).

Experimental QKD networks have been realized in USA, Europe, Japan, China, and Korea. The limited QKD range caused by photon state decoherence is extended by multi-hop networking with trusted nodes and QKD combined with the absolutely secure OTP (One Time Pad) encryption (Bellovin, 2011). China has in autumn 2015 almost completed installation of the world's hitherto largest quantum communications network, 2000 kilometers from Beijing to Shanghai. (Elliot, 2004; Poppe et al., 2008; Gisin, 2015; Fadilpašić, 2015)

Quantum Key Agreement

Subramaniam and Parakh (2014) propose a quantum Diffie-Hellman protocol. Two parties, Alice and Bob, agree on a basis set to use, the number m of qubits to exchange, and the initial qubit state $|\psi\rangle = |0\rangle$. Every basis consists of two rotation transformations, R for bit value 0 and $R+90^\circ$ for value 1, where $R=0^\circ$ or 30° or 42° etc. Then Alice and Bob independently and randomly choose m bases from the agreed set, generate a sequence of m random bits, and send a m qubit sequence to each other.

Each sent qubit is a rotation of $|\psi\rangle$ determined by the chosen basis and the generated bit. Alice and Bob then:

- Apply to each received qubit a rotation determined by the chosen basis and the generated bit,
- Apply the rotation 90° -(previous rotation angle),
- Record the bit from measuring the rotated qubit in the chosen basis.

Both Alice and Bob thus obtain an m bit sequence from received qubits and can now announce their chosen basis sequences to each other over a public channel. A bit in the obtained sequence is discarded, if Alice and Bob use a different basis. The resulting shared secret key is a joint random selection from the remaining bits. Third party interference in qubit transmission causes bit errors.

Quantum Secret Sharing (QSS)

The first QSS used the GHZ entanglement state (Hillery, Buzek, & Berthaume, 1999). QSS protocols have two types defined by the entanglement and product states. Zhang and Man (2005) propose a protocol based on entanglement swapping and local unitary operation. Tan, Feng, Jiang, and Fang (2013) present a verifiable quantum secret sharing protocol based on entanglement swapping. External eavesdroppers, internal cheaters, and cheating by two cooperating dishonest participants are prevented.

Information-Flow Security of Quantum Systems

Entanglement can cause Information leakage. A Trojan horse may exploit entanglement between itself and a user with sensitive information as a covert channel (Ying, Feng, & Yu, 2013). The noninterference formalism is a general framework for specifying and analyzing information-flow security.

Quantum Digital Signature

Classical digital signatures can be created with any one-way function (Lamport, 1979). A secure quantum one-way function based scheme for signing classical bit strings is proposed in (Gottesman & Chuang, 2001), patented in USA (Chuang & Gottesmann, 2002), and experimentally demonstrated in (Clarke et al., 2012). Lu and Feng

(2005) propose another quantum one-way function based scheme for signing general quantum states. Quantum message authentication can be based on quantum signature schemes (Barnum, Crepeau, Gottesman, Smith, & Tapp, 2002).

QUANTUM ERROR CORRECTION

Quantum state decoherence, quantum noise, faults in quantum gates and qubit memories, and faulty qubit state measurements cause errors. Quantum error correction methods, codes, and algorithms are therefore required. (Lidar & Brun, 2013)

Nielsen and Chuang (2002) describe quantum circuits for single qubit flip error correction. Reed et al. (2012) present superconducting circuits for three-qubit quantum error correction. A superconducting quantum computing chip, a 4 qubit square lattice, has been designed and successfully used to detect arbitrary single qubit errors (Córcoles et al., 2015).

FUTURE RESEARCH DIRECTIONS

Research aiming to build a large scale quantum circuit based computer will continue. Possible solutions are a multiple of two qubit gates in silicon (Veldhorst et al., 2015) and superconducting qubits in a two-dimensional grid (Córcoles et al., 2015; Simonite, 2015).

Future quantum computers will probably combine a classical and a quantum device. Computations are decomposed into a controlled set of subtasks. The quantum device executes subtasks, for which efficient quantum algorithms can be programmed, and some control, the classical device executes other subtasks and control. (Nielsen & Chuang, 2002)

Additional polynomial quantum algorithms are being investigated to solve so called hidden subgroup problems, to which integer factoriza-

tion belongs. New and more powerful quantum programming languages, mainly functional, will be developed. (Sofge, 2008)

A new technique using twisted light will increase the efficiency of quantum communication. Polarization encodes only one bit per photon but the new technique, Orbital Angular Momentum, encodes 2.05 bits per photon and may still be extended. (Mirhosseini et al., 2015)

Lack of fast photon detectors limits QKD performance. New detectors based on cryogenic niobium nitride superconductors may be a solution (Quellette, 2004). Research on ideal single-photon sources continues, since multiple photon emissions are vulnerable. Expected future QKD advances (Hogben, 2009):

- Increased QKD *distance* with quantum repeaters
- Increased transmission rate
- Decreased QKD *costs*
- Perfectly random OTP keys from quantum state measurements in *Quantum Random Number Generation*.

CONCLUSION

Future quantum computing can erode security of current public key cryptography. The vulnerability of RSA based cryptography to quantum integer factorization is evident. Also current Elliptic Curve Cryptography is vulnerable to quantum algorithm attacks (Maslov, Mathew, Cheung, & Pradhan, 2009). Quantum resistant public key cryptography is thus a future need. Proposed candidates are Lattice Based Public-Key Cryptography, Multivariate Public-Key Cryptography, Code-Based Public-Key Cryptography, Hash-Based Signatures, McEliece Cryptosystems and a revised Elliptic Curve Cryptography (Buchmann, 2015; Zhang & Xu, 2014; Perlner & Cooper, 2009; Jao & de Feo, 2011). Also a quantum resistant SSL/TLS protocol has been proposed (Chang, Chen, Wu, & Yang, 2014).

Future quantum computing also affects symmetric cryptosystems. Grover's quantum algorithm halves brute force search bit length. For example, quantum attack resistance of 256 bit AES is 128 bit.

Quantum cryptography is an emerging information security technology, which is presently already available but still neither fully integrated in current network technology nor standardized. Technological limitations regarding quantum transmission distance and quantum device technology need to be removed.

KEY TERMS AND DEFINITIONS

AQC: Adiabatic quantum computation, calculation by quantum annealing.

Avalanche Photodiode: The semiconductor analog to a photomultiplier.

Decoherence Time: The time a qubit state prevails before collapse.

Entanglement: A multiple qubits state which cannot be created by combining single qubit states.

Photon: A discrete packet of electromagnetic energy.

Polarization: The propagation plane of an electromagnetic wave.

Quantum GATE: A device changing the state of one or multiple qubits.

Qubit: A two-state quantum-mechanical system which can be a concurrent superposition of both states.

Teleportation: Transfer of a qubit state.

Sleptsov Net Computing

T

Dmitry A. Zaitsev

International Humanitarian University, Ukraine

INTRODUCTION

Recently many researchers introduce new models of hyper-computations, such as quantum computations, computations on cell membranes, spiking P neurons and DNA (Cook & Neary, 2013), capable breaking through the obstacle of intractable tasks. Petri nets have been known for years as a model of concurrent systems (Murata, 1989) but their computationally universal extensions are exponentially slow comparing Turing machines, especially when implementing arithmetic operations. A Sleptsov net concept, suggested quarter a century ago, recently acquired its second birth (Zaitsev, 2016) due to its ability of fast implementation of basic arithmetic operations. Firing a transition in a few instances at a step leads to universal constructs which run in polynomial time (Zaitsev, 2017). In Sleptsov net computing (Zaitsev, 2014a; Zaitsev & Jürjens, 2016), a program, written in Sleptsov net language preserving concurrency of an application area, runs on Sleptsov net processor which implements concurrent firing of transitions in multiple instances providing computations having ultra-performance.

BACKGROUND

A concept of algorithm was formalized for the first time by Alan Turing in 1936 in the form of an abstract machine which is traditionally called a Turing machine. Universal Turing machine which runs a given Turing machine is considered a prototype of a traditional computer. Besides Turing machines, other computationally universal systems appeared: recursive functions of Kleene, normal

algorithms of Markov, tag rewriting systems of Post, register machines of Minsky. Variety of models is explained by controversial requirements of manifold application areas. Recent models employ facilities of massively parallel computations even in such simple constructs as elementary cellular automata which universality was proven in 2004 by Mathew Cook. Besides, smallest universal Turing machines were constructed in 2008 by Turlough Neary and Damien Woods which run in polynomial time. However, the way of programming cellular automata after Mathew Cook does not reveal their ability for massively parallel computing. Sleptsov net concept (Zaitsev, 2016) mends the flaw of Petri nets (Murata, 2013), consisting in incremental character of computations, which makes Sleptsov net computing (Zaitsev, 2014a; Zaitsev & Jürjens, 2016) a prospective approach for ultra-performance concurrent computing. In Zaitsev (2016), an overview of works, which refer to Sleptsov nets (Petri nets with multichannel transitions or multiple firing strategy), is presented.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Definition of Sleptsov Net

A *Sleptsov net* (SN) is a bipartite directed multi-graph supplied with a dynamic process (Zaitsev, 2016). An SN is denoted as $N=(P,T,W,\mu_0)$, where P and T are disjoint sets of vertices called *places* and *transitions* respectively, the mapping F specifies *arcs* between vertices, and μ_0 represents the initial state (*marking*).

DOI: 10.4018/978-1-5225-2255-3.ch672

The mapping $W: (P \times T) \rightarrow \mathbb{N} \cup \{-1\}$, $(T \times P) \rightarrow \mathbb{N}$ defines arcs, their types and multiplicities, where a zero value corresponds to the arc absence, a positive value – to the *regular arc* with indicated multiplicity, and a minus unit – to the *inhibitor arc* which checks a place on zero marking. $\mathbb{N}$ denotes the set of natural numbers. To avoid nested indices we denote $w_{j,i}^- = w(p_j, t_i)$ and $w_{i,j}^+ = w(t_i, p_j)$. The mapping $\mu: P \rightarrow \mathbb{N}$ specifies the place marking.

In graphical form, places are drawn as circles and transitions as rectangles. An inhibitor arc is represented by a small hollow circle at its end, and a small solid circle represents the abbreviation of a loop. Regular arc's multiplicity, greater than unit, is inscribed on it and place's marking, greater than zero, is written inside it. Examples of SNs computing basic arithmetic and logic operations are shown in Figure 6.

To estimate *multiplicity of firability conditions* on each incoming arc of a transition, the following auxiliary operation is defined

$$x \succ y = \begin{cases} x / y, & \text{if } y > 0 \\ 0, & \text{if } y = -1, x > 0, \\ \infty, & \text{if } y = -1, x = 0. \end{cases}$$

To avoid inconsistency with infinite number of instances, here we prohibit transitions without input regular arcs.

The behavior (dynamics) of a SN could be described by the corresponding state equation similarly to (Zaitsev, 2012). The present work considers the behavior as result of applying the following *transition firing rule*:

- The number of instances of transition t_i firable at the current step is equal to

$$v_i = v(t_i) = \min_j (\mu_j \succ w_{j,i}^-), 1 \leq j \leq m, w_{j,i}^- \neq 0$$

- When transition t_i , $v_i > 0$ fires, for $u_i \leq v_i$ it
 - extracts $u_i \cdot w_{j,i}^-$ tokens from each its input place p_j for regular arcs $w_{j,i}^- > 0$;
 - puts $u_i \cdot w_{i,k}^+$ tokens into each its output place p_k , $w_{i,k}^+ > 0$;
- The net halts if firable transitions are absent.

When a transition, having a single regular incoming arc with multiplicity a from place p and a single regular outgoing arc with multiplicity b to place p' , fires with $u_i = v_i$, it implements the following computations $\mu(p) = \mu(p) \bmod a$; $\mu(p') = \mu(p') + b \cdot (\mu(p) \text{ div } a)$. Namely, it implements division by a with a remainder and multiplication by b . Choosing either a or b equal to unit we obtain either pure multiplication or pure division.

In Petri net, only one transition fires at a step while in Sawicki net (Burhard, 1981) a maximal set of firable transitions fires at a step. However in both Petri and Sawicki nets, only one instance of a transition fires at a step.

Transitions could be thought of as virtual actions. The number of really started actions depends on the amount of available resources represented by transitions' input places. Why we should restrict the number of transitions' instances to unit and fire them in sequence, as in Petri net, when available resources allow firing them simultaneously? Anyway, classical sequential order of transitions' firing could be obtained as a special case attaching a place to each transition connected with read arc and having marking equal to unit.

Various extensions of Petri nets are known such as priority, inhibitor, timed, loaded (colored), hierarchical, and nested Petri nets (Murata, 1989). Sometimes they sophisticate the basic model considerably. Our goal consists in obtaining hyper-performance at the cost of minimal modification which consist in the multiple firing

strategy. As for other concepts concurrent to Petri nets, multiset rewriting systems (Verlan, 2011) should be mentioned as well as vector addition and replacement systems. Moreover, for studying protocols, the concept of Hoare's communication sequential processes is close to Petri nets and mutual transformations are possible. An essential advantage of Petri (and Sleptsov) nets is graphical presentation of systems' structure and behavior.

Universal Sleptsov Net as a Processor

When programming in Sleptsov (Petri, Salwicki) net language, we use a concept of dedicated contact places. Before a net starts, we upload input data into its contact places, and when a net halts, we download output data from its contact places. Sometimes deeper specialization is more convenient when we distinguish separate subsets of input and output places. Note that data of various data types are encoded as nonnegative integer numbers to be processed by a net.

Turing-completeness of extended PNs means that a universal net, which runs a given net, exists. Recently a series of small universal Sleptsov nets was constructed (Zaitsev, 2017, 2014b) in which each net of the series can be considered a prototype of a processor in a Sleptsov net based computer (Zaitsev, 2014a). A program of such a computer, composed in the form of a (inhibitor) Sleptsov net and encoded, is given as an input to

a processor which represents a hardware implementation of a universal Sleptsov net; Figure 1 illustrates the approach.

The main obstacle for wide implementation of the Petri net paradigm of computation (Zaitsev, 2014a) has been the fact that all known small universal nets run in exponential time. In (Zaitsev, 2017), a small universal Sleptsov net was constructed which runs in polynomial time; the net contains 15 places and 29 transitions. Technique of a universal SN composition (Zaitsev, 2017) using reverse control flow and subnets for multiplication and division by a constant is handy for developing the technology of programming in SNs. The considerable complexity difference between universal PNs and universal SNs is easily explained: when processing the TM tape code, which is an exponent on the working zone size, a universal PN takes a single token at a step while a universal SN takes all of the tokens; eventually, we come to arithmetic operations, namely multiplication and division employed for encoding/decoding input PN.

In (Zaitsev, 2014a) we offer a computing memory concept for massively parallel asynchronous implementation of SN processors that promises ultra-performance when processing programs written in SN language. Apart from the problem of efficient hardware implementation of a SN computer, an issue arises regarding the technology of programming in SNs and preserving natural parallelism (concurrency) of an application area.

Figure 1. Universal net as a processor

Universal Sleptsov Net Runs in Polynomial Time

Similar to (Zaitsev, 2014b, 2017), we construct a universal SN via simulation of weakly-universal Turing machine of Neary and Woods with 2 states and 4 symbols denoted as WUTM(2,4). As far as Turing machine behavior is deterministic, we use deterministic SN where transitions are enumerated and the firable transition with the least index fires in the maximal number of instances. For visual reflection of the transitions order (priority), we use arcs connecting transitions; if there is an arc from transition t to transition t' , it means that index of transition t should be less than index of transition t' (lesser index means higher priority here). The peculiarity of programming in SN is application of reverse control flow represented with moving zero marking; thus the initial marking of control flow places is equal to 1. We check zero marking via an inhibitor arc which does not restrict the multiplicity of firability conditions.

The source information for simulation is the transition function of WUTM(2,4) and the encoding of its states and tape symbols (Zaitsev, 2017) given by Table 1. In WUTM(2,4), an infinite repetition of definite blank words is written on its tape: $b_l = 00\emptyset 1$ to the left and $b_r = 0\bar{1}\emptyset\emptyset 1$ to the right of the working zone. According to the function $s(x_{k-1}x_{k-2}\dots x_0) = \sum_{i=0} s(x_i) \cdot r^i$ for the tape words' encoding, the codes of the left and right blank words are: $s(b_l)=167$ and $s(b_r)=13596$.

The constructed universal Sleptsov net is denoted as USN(15,29) with respect to the total number of its places and transitions, respectively.

The general scheme of USN(15,29) is shown in Figure 2a. Subnets are depicted as rectangles with double line border. Some vertices have mnemonic names besides their numbers. Used subnets FS, MA5LR, and MD5LR are represented in Figure 2b, Figure 2c, and Figure 2d, respectively. Places with the same name (number) are considered as the same place and should be merged all over the components. The final assembly of USN(15,29) drawn in (Zaitsev, 2017) looks rather tangled.

Place U contains encoded TM state $s(u)$, place X contains encoded current cell symbol $s(x)$, and places L and R contain encoded left and right parts of the tape working zone respectively regarding the current cell. At the beginning of each computation step, place STEP launches subnet FS, which simulates WUTM(2,4) transition function. Subnet FS produces the encoding $s(u')$ of the new state and the encoding $s(x')$ of the new symbol in places U and X respectively to simulate the Turing machine instruction. Subnet FS also puts a token into either place RIGHT or place LEFT to indicate the control head right or left moves correspondingly. A token is extracted from place MOVE after subnet FS has finished that launches the sequence of subnets MA5LR, MD5LR, which simulates the control head moves. At the end of a simulated computation step, a token is put into place STEP that allows the simulation of the next instruction to begin. Moreover, places LEFT and RIGHT are cleared.

The TM tape is represented by the places L, X, and R containing the encoded left part of the working zone, the current cell symbol and the encoded right part of the working zone correspondingly. The moves of the tape head on the tape are

Table 1. Weakly-universal Turing machine WUTM(2,4) and its encoding

Σ/Ω	$s(\Sigma)/\sigma(\Omega)$	u_1	u_2
		0	1
0	1	3,left,0	4,right,0
1	2	4,left,1	3,left,1
$\emptyset$	3	4,left,0	1,right,1
$\bar{1}$	4	4,left,0	2,right,1

Figure 2. Component-wise representation of USN(15,29)

simulated by the two connected subnets MA5LR and MD5LR shown in Figure 2c and Figure 2d, respectively. The meaning of subnets' names is the following: MA5 means multiplication and addition with radix 5 ($S := S \cdot 5 + X$); MD5 means modulo and division with radix 5 ($S := S \text{ div } 5$, $X := S \bmod 5$); LR means choice of places either L or R, where codes of the left and right parts of the tape, regarding the current cell symbol code X, are stored, depending on the marking of places LEFT and RIGHT.

Two transitions lb and rb simulate peculiarities of weakly universal TM work, they add the blank word codes $s(b_l)$ and $s(b_r)$ to the codes L and R of the left and right parts of the tape working zone correspondingly when its value is equal to zero.

Thus, the sequence of subnets MA5LR, MD5LR implements the following operations:

- To simulate a left move (when place RIGHT=0): $R := R \cdot 5 + X$, $L := L \text{ div } 5$, $X := L \bmod 5$;
- To simulate a right move (when place LEFT=0): $L := L \cdot 5 + X$, $R := R \text{ div } 5$, $X := R \bmod 5$.

In (Zaitsev, 2017), it was proven that USN(15,29) simulates WUTM(2,4) in time $O(14 \cdot k)$ and space $O(k)$, where k is the number of WUTM(2,4) steps. Taking into consideration polynomial complexity of running a TM on WUTM(2,4) and polynomial complexity of running an SN on TM, we obtain the final polynomial complexity of the constructed universal Sleptsov net.

Principles of Programming in Sleptsov Nets

Programming in SNs (Zaitsev & Jürjens, 2016) represents a composition of data and control flows supplied with transition substitution to describe hierarchical structure of routines (nets). We suppose that to combine control flow with a subnet which substitutes a transition, a special pair of places is used: *Start* – to launch the subnet and *Finish* – to indicate its completion.

Control flows are represented in an inverse form with a moving zero marking because a zero marking is easily checked via an inhibitor arc that does not restrict the number of fireable instances

of a transition. Thus, initially, all control flow places should have marking equal to one.

To simulate standard control flows of classic programming languages, we offer the patterns represented in Figure 3 for a sequence a), branching b), cycle c), and parallel execution d). Moreover, an arbitrary subnet with markings belonging to $\{0,1\}^m$ and with a pair of start/finish places could be considered as a control flow.

Each of transitions in Figure 3 could be substituted by a subnet using its input place to start it and its output place to indicate its completion. Moreover, additional incidental places could be attached which represent required input and output variables. In the patterns with alternative transitions (Figure 3 b, c), we suppose either an external control via conditional variables to make it deterministic or nondeterministic choice.

For computation of expressions, a data flow approach seems more efficient when a corresponding subnet is started and finished with an external control flow. It is a question of granulation whether to use strict composition of subnets launched via

control flow or to write anew a closely connected tangle of control and data flows where each of them is not even clearly distinguished.

A program written in Sleptsov nets is obtained via composition of control flows with data flows using a modular approach. Substitution of a transition by a module is defined by the indication of the module name and connection (mapping) of its input and output places with places of a net which either represent variables or control flow.

It is also supposed that before a module starts, all of the input data is copied into its input places while after a module finishes and before its next start, all the output data is moved from its output places. For these purposes dashed arcs were introduced (Zaitsev, 2012) to designate a brief and convenient way of working with data.

A dashed input arc of a module denotes a subnet COPY for copying an input variable value into the corresponding input place of the module before launching its work via the place *Start*. A dashed output arc of a module denotes a sequence of subnets CLEAN, MOVE for replacing a variable

Figure 3. Standard control flow patterns

value with the result obtained in the corresponding output place of module. When a module has a few input (output) places, the subnets COPY (CLEAN, MOVE) are inserted using the parallel execution pattern (Figure 6). An example is shown in Figure 4 a,b where subnet a) having dashed arcs is expanded into the corresponding low-level subnet b).

Introduced for reduction in auxiliary subnet size, dotted arcs denote MOVE for both input and output variables; MOVE subnet is more concise and provides cleaning of its input variable. Thus, the value of the input variable is not preserved and the value of the output variable is incremented. When the same variable is both input and output, a dotted two-direction arc is used which is expanded as MOVE before launching a module and MOVE after finishing the module. The corresponding example is shown in Figure 4 c, d where subnet c) having a dotted arc is expanded into the corresponding low-level subnet d).

Thus, a module could be considered as a programming language procedure whose contact places correspond to its formal parameters. Copying variables with dashed and dotted arcs

correspond to the substitution of the actual input parameters and extracting its output parameters. The question remains open regarding the way a module call can be implemented either using an inline fashion via cloning entire modules or a call-return fashion via having a single copy of a module and switching control flows. The difference between the two mentioned ways is illustrated in Figure 5 for two references to the addition module ADD (without considering data). While the call-return fashion is more concise because of having a single copy of a module, the inline fashion is more attractive from the concurrent execution point of view (Zaitsev, 2014a).

A program composed of modules is finally compiled into a plain inhibitor priority Slepsov net that is loaded for execution on a SN computer. The best performance is achieved when all the transitions are fired independently based on their fireability conditions; to resolve conflicts a special arbiter is provided which blocks incidental places of a firing transition. This way of execution also requires writing programs which are invariant to the transitions' firing order.

Figure 4. Examples of dashed arcs expansion

Figure 5. Example of transitions' substitution implementation for $z1=ADD(x1,y2)$; $z2=ADD(x2,y2)$ 

Efficient Implementation of Arithmetic and Logic Operations

To describe the transition substitution operation in a formal way, regarding an external control flow and input/output variables, a concept of *module* is introduced (Zaitsev, 2016). A module represents a subnet with contact (input and output) places which could be either the only connection with the outside world for closed modules or combined with the global variables usage for open modules. The module work is controlled via a special pair of contact places: place *Start* (*s*) starts work, and place *Finish* (*f*) indicates the completion of a module's work.

Extracting a token from the first control flow place *Start* launches the moving zero marking till it arrives to the last control flow place *Finish*. We put the following restrictions on the control flow graphs. It is supposed that all actions of a module are controlled by its control flows and inhibitor arcs are used to fire a transition. Thus, when all the control flow places contain a token, the module transitions are disabled. Therefore, before extracting a token from the place *Start* as well as after the arrival of zero to the place *Finish*, the module stands still.

To provide the re-enterability of a module, it is supposed that: when it starts, all its data places except input places have zero marking, and when it finishes, all its data places except for output places have zero marking. In Figure 6, nets are represented which implement basic copying, arithmetic and logic operations. Compared to (Zaitsev, 2012), subnets are reduced by one place and one transition under the assumption that we can use the input place *Start* to control transitions inside a subnet, but the place *Finish* is not used for the control inside a subnet.

Using the technique of analyzing all the permitted fireable transition, employed in (Zaitsev, 2014b), we can prove that the subnets represented in Figure 6 implement the corresponding operations.

For classic Petri nets, operations of multiplication and division are the most complex from the computational point of view; the corresponding subnets were studied in (Zaitsev, 2012). Namely their complexity influences the exponential slowness of computations on Petri nets. Considered in (Zaitsev, 2017), fragments of the universal Sleptsov net efficiently implement multiplication and division by a constant (equal to 5). Now we study multiplication and division of arbitrarily

given nonnegative integers using multiplication and division by a constant (equal to 2).

We choose simple standard algorithms of long multiplication and division. The best known efficient algorithms of multiplication and division for natural numbers could be encoded in SN as well. The multiplication algorithm represents the usual “long multiplication”. To find the current digit of the multiplier, the remainder of the division by two $d=y\%2$ is used; then the multiplier is recalculated via $y/=2$ for working with the next digit on the next pass of the main loop. The multiplicand is multiplied by two $x*=2$ which represents its shift to the left. When the current digit d of the multiplier is equal to 1, the shifted multiplicand is added to the result. The algorithm could be optimized to avoid recalculating $x*=2$ when the new value of y is equal to zero but it leads to a more sophisticated SN. The algorithm was encoded as a SN and is represented in Figure 7.

For Sleptsov nets shown in Figures 6 and 7, it has been proven (Zaitsev, 2016) that:

- CLEAN, MOVE, COPY, NOT, OR, AND, ADD, SUB, GT0, GT implement corresponding operations with time and space complexity equal to a constant;

- MUL implements multiplication of non-negative integer numbers x and y with time complexity $O(11 \cdot \log_2 y + 3)$ and constant space complexity (equal to 15);
- DIV implements division of nonzero integer numbers x by y with time complexity $39 \cdot (\log_2 x - \log_2 y) + 19$ and constant space complexity (equal to 48).

MUL(x, y): $z := x \cdot y$, $x := 0$, $y := 0$;

DIV(x, y): $z := x/y$, $r := x\%y$, $x := 0$, $y := 0$.

As an example, to calculate $3 \cdot 2 = 6$, the number 3 is loaded into place X (p_1) and the number 2 is loaded into place Y (p_2). To start computations, a token is removed from place S (p_3). Then the only enabled firing sequence

$$t_1 t_5 t_6 t_8 t_{10} t_{11} t_{12} t_{13} t_{14} t_{16} t_1 t_6 t_7 t_8 t_9 t_{11} t_{13} t_{14} t_{15} t_2 t_3 t_4$$

leads to obtaining the result 6 in place Z (p_4) which is indicated by the removal of a token from place F (p_5).

Note that, the multiplication SN module shown in Figure 7 multiplies given natural numbers X and Y , and uses for this purpose multiplication

Figure 6. Modules which implement basic operations: copying, logic, and arithmetic

Figure 7. Modules which implement multiplication and division

and division by the constant 2 implemented with a single SN transition; multiplication and division by constant 2 are usually efficiently implemented as the left and right shift of binary code correspondingly.

The division algorithm represents the usual “long division”. An initial dividend x is split into two parts. Namely, x which represents its head comparable to y and its tail tx . The first loop *while*($y \leq x$) implements the splitting via obtaining separate digits d from the left of the tail using modulo operation $d = x \% 2$ while x is truncated of the last digit via division operation $x = x / 2$. The obtained digits are appended to the left of the tail using $tx = tx * 2 + d$. The branching *if*($n > 0$)

moves the separation one digit back when possible guaranteeing that x is the minimal possible head that is greater than y .

In a real-life implementation, either hardware or software, of SN as well as PN, we should consider the complexity of the above mentioned procedures. Supposition of a sequential computation device (Zaitsev, 2014b) yields the multiplier $O(|P| \cdot |T| \cdot \log_2 l)$ for PNs, where l is the maximal number of steps. For SNs, an extra complexity of multiplication and division by a constant equal to a power of 2 is also estimated as $O(\log_2 l)$; for an arbitrary constant the complexity is sublinear. If we suppose some independent computing memory device implements each transition (Zaitsev, 2014a),

we get rid of the multiplier $|P| \cdot |T|$ and obtain an ultra-parallel processor of Sleptsov nets with step complexity $O(\log_2 l)$.

The considered estimations are too meticulous for usual comparisons of arithmetic algorithms. Supposing that x and y contain about n binary digits $x \approx y < 2^n$ and using the logarithmic scale with the multiplier $\log_2(x \cdot y) \approx 2 \cdot n$, we obtain the multiplication complexity $O(2^{2n})$ for PNs and $O(n^2)$ for SNs. For the division operation, we suppose that x contains $2 \cdot n$ binary digits and y contains n binary digits. Then we obtain the division complexity $O(2^{2n})$ for PNs and $O(n^2)$ for SN. Thus, SNs run faster comparing PNs. For multiplication and division operations, SNs run in polynomial time while PNs require exponential time.

Note that some SNs can be interpreted as PNs giving the same result but with a certain slowdown of execution. The investigation of such equivalence is a direction of future work.

SOLUTIONS AND RECOMMENDATIONS

From the described above implementations of universal Sleptsov net and Sleptsov nets for arithmetic operations having polynomial time complexity, we conclude that they run exponentially faster than Petri nets and recommend their application as a

new kind of concurrent computing (Zaitsev, 2016). Basics of Sleptsov net programming perceived as a composition of data and reverse control flow were developed.

Computations on SN gain wide application. We complete the article with three examples described in (Zaitsev, 2016) from rather diverse areas such as data encryption with open key, soft computing with fuzzy logic, and parallel and distributed computing shown in Figure 8, 9, 10, respectively. The first net use studied subnets for arithmetic operations and additional subnet REV for reversing the bitwise representation of z while the second and third nets implement logic and arithmetic operations directly via SN transitions.

We recommend SN computing in the first place for application areas where concurrent style of programming is advised and brings considerable speed-up of computations.

FUTURE RESEARCH DIRECTIONS

Practical implementation of Sleptsov net computing requires ad-hoc CASE-systems development and hardware implementation of Sleptsov net processors. From theoretical point of view, issues of proving correctness of Sleptsov net programs and design of universal Sleptsov nets, which employ massively parallel approach, are in demand.

Figure 8. RSA encryption/decryption $y = x^z \bmod n$;

Figure 9. Calculating fuzzy logic function $\varphi = x_1 \bar{x}_2 \vee \bar{x}_1 x_2 = ((x_1 \bar{x}_2) \wedge (\bar{x}_1 x_2))$;

Figure 10. Solving Laplace equation $\frac{\delta^2 \varphi}{\delta x^2} + \frac{\delta^2 \varphi}{\delta y^2} = 0$.

CONCLUSION

The article studies a more general class of place-transition nets introduced by Anatoly Sleptsov, which allow a transition firing in multiple instances at a step. It was shown that Sleptsov nets run exponentially faster than Petri nets. A small universal inhibitor Sleptsov net runs in polynomial time and could be considered as a prototype of a SN processor devised for executing programs written in a SN language. Efficient massively parallel implementations of SN processors are discussed in (Zaitsev, 2014a).

Basics of Sleptsov net programming technology were developed including efficient implementation of arithmetic and logic operations, as well as rules of program composition via combination of data and control flows and substitution of transitions. Sleptsov net computing has such advantages as concurrent programming style, concise graphical language and small granulation of parallel processes on the level of separate events which promise hyper performance.

KEY TERMS AND DEFINITIONS

Algorithm: A declaration of a stepwise process of computations; the order of steps precisely prescribed; at each step exactly known how to obtain a result from the source data.

Computationally Universal System: A system capable to execute (run) a given algorithm.

Place-Transition Net: A directed bipartite graph with a dynamic process defined on it.

Petri Net: A place-transition net where one transition fires at a step.

Salwicki Net: A place-transition net where the maximal set of firable transitions fires at a step – maximum firing strategy.

Sleptsov Net: A place-transition net where a transition fires at a step in a few copies – multiple firing strategy.

Turing Machine: An abstract machine consisting of infinite tape and a control head; was introduced by Alan Turing in 1936 as a formalization of the algorithm concept.

Ubiquitous and Pervasive Computing

Energy Conservation in the Era of Ubiquitous Computing

P. P. Abdul Haleem
Farook College, India

INTRODUCTION

The widespread availability of computing devices and easy access to the Internet has revolutionized the way people use computers. Computers and computing devices became so common and popular among the people of all walks of life. Advances in the technology pave way to computing devices that can be carried with users wherever they are – hence paving a new era called as “ubiquitous computing”. The barriers such as type of devices, location, time and format has become meaningless in this era (Mark, 1999). Other terminologies used for ubiquitous computing include pervasive computing, ambient intelligence (Hansmann, Merk, Nicklous, & Stober, 2003), ambient media (Artur, Thomas, Bjoern, Kari, & Juha, 2009) or everywhere (Adam 2006).

Ubiquitous computing resulted in a paradigm shift from the hitherto computing called desktop computing: (i) the traditional wired networks had to be extended to include wireless networks, and (ii) the concept of anywhere computing was materialized with the introduction of devices that are mobile and wireless. The extension of traditional wired network into wireless network resulted in a lot of challenges due to the reason that existing protocols and supporting software had to be extended to include wireless arena also. The introduction of wireless mobile devices also demanded a lot from the research and developer community for their smooth existence and interactions within a network.

When the facility of anywhere computing becomes the rule of the day, one of the main issues it raises is energy consumption. This is due to the

following reasons: (i) majority of the devices engaged in ubiquitous computing are mobile wireless devices, (ii) mobile wireless devices depend on the attached battery for their power requirements, (iii) the challenge of “packing” energy with the limited “real estate” available with a hand held device, and (iv) even if significant improvements have been achieved in the battery technology, the pace of development is not in par with the developments in the microprocessor design (Christopher 2014).

Due to the inherent deficiencies of battery power, devices engaged in ubiquitous computing have further headaches concerning their battery power. The energy consumed by the devices is depending on many factors such as the type of gadgets used in the assembly/make of the device, type of usage of the device (mobile or fixed), type of applications and networks onto which the device is getting connected (Internet Users, 2015).

In this chapter, the scope is limited to the energy consumption issues related to the web connectivity. This is due to the fact that Internet is the most viable and readily available infrastructure to hook the entire world into a web. In the era of ubiquitous computing, the majority of the users are getting connected to the Internet for their heterogeneous types of needs and applications. As of July 2016, the total number of Internet users in the world crossed three and half billion – 4% of the world’s population (Internet Users, 2016).

BACKGROUND

Main cause of energy consumption especially in hand held devices are usage of Internet. In this

section a brief account of the internet usage and energy consumption is outlined.

INTERNET USAGE

The popularity of smart devices used in the ubiquitous computing continues to grow at an exponential rate. This is due to the affordability of devices and availability of 3G, 4G and 5G networks. Currently there are as many mobile devices all over the world, as there are computers. The availability of smart phones is also increasing to the extent that global smart phone activations outnumber global child births by three to one (Tom, 2014). Trends reveal that smart phone customers are expected to reach 2.08 billion by 2016 (Statista, 2016).

This tremendous growth of devices (smart phones and feature phones with Internet connectivity) has its impact over the Internet traffic also. The Internet traffic is steadily increasing at the rate of 66% per year (Internet Live Stats, 2015). In the past five years Internet traffic has quintupled (World Wide Web, 2016). It is estimated that monthly global mobile data traffic will surpass 15 exabytes by 2018 (Cisco, 2016). Internet offers a bunch of services to the users at an affordable cost. The popularity of the services offered by the Internet is an indicative to the degree of the obsession the users across the world have developed with the Internet.

World wide web (WWW) is the foremost service offered by the Internet. The ease of use, easy access to the WWW and wide popularity of devices which can be used to access the Internet caused an exponential growth in terms of number of users logged on, devices used and data shared over the websites. WWW, one of the biggest repository of information in the world, is getting expanded in terms of its variety, veracity, velocity and volume - from just one web site in 1991 to 1 billion web pages in 2014 (World Wide Web, 2016).

When there is a variety of information available at WWW, the process of finding the required web pages will also increase. Search engines are

widely used to locate the pages of one's interest. It is estimated that Google processes over 40,000 search queries every second on average - over 3.5 billion searches per day and 1.2 trillion searches per year worldwide (Google Search Statistics, 2015). The types of queries being fired are unique in the sense that 16% to 20% of queries that get asked every day have never been asked before (Mitchell, 2012). Queries made using mobile devices are also increasing day by day. It is found that the time spent on Internet using mobile devices in USA exceeds the time spent using desktop PCs during February 2013 and January 2014 (Rebecca 2014). Studies reveal that more than 90 percent of Internet users will access online content through their phones in 2017 (Internet Usage Statistics, 2015).

The evolution of web technology from read-only static pages to readily updatable dynamic pages has contributed a lot to the increased traffic over Internet – this evolution gave birth to a class of web sites known as social media. Social media is being effectively used as a platform for many innovative ideas and needs such as political campaigns, job applications, business promotion and networking, religious campaigns, educational purposes, and customer services. One of the reasons behind the popular use of WWW is the emergence of social media.

As of July 2014, there are 106,000,000 active social media users in India. However this is not a big number considering the fact that out of the 1.25 billion people in India, only one-fifth of the people use Internet and only 50% of these are using social media (Bhavya, 2014). But when the worldwide activities are considered, the statistics are astonishing. Number of postings made by the users on Facebook reached nearly 2.5 million. Contents uploaded to YouTube amounts to 72 hours of content. Number of tweets on Twitter crossed 277,000, Vine users shared 8,333 clips, WhatsApp users share 347,222 photos, and Instagram users share 216,000 new photos per minute (Kimberlee, 2014). In addition to this people also make use of WWW for their needs such as shopping, attending seminars and online courses.

Email is another important service offered by Internet. Both text and multimedia attachments can be accompanied with an email message. An email message can be replicated to a large set of users. Internet users send more than 200 million emails every minute (Kimberlee, 2014). Number of mobile email users in the world is expected to reach 2.83 billion by the end of 2017 (Karl, 2013).

Short Messaging Service (SMS) is a service offered by mobile service providers as a cheap and user-friendly service to exchange messages. Internet based services are also becoming viral now a days that can be used to exchange multimedia information. Such services are called as over-the-top content (OTT) services. Estimates reveal that SMS traffic worldwide will peak at 8.3 trillion messages annually in 2015 (Kimberlee, 2014). But due to the popularity of OTT messaging apps, volume of messages sent by these apps are also increasing. It is predicted that by the end of 2017, there will be over 2.5 billion OTT messaging apps users. Subsequently the number of OTT messages are also increasing - OTT message traffic will exceed 32 trillion messages annually by 2017 (Kimberlee, 2014). Available trends indicate that eventually OTT messages will surpass SMS messages – it really happened in UK in 2014 (Luke & Sean, 2014).

It can be concluded that the explosive growth of Internet and expansion of ubiquitous computing have complemented each other – in terms of the number of devices, users and network traffic.

CONSUMPTION OF ENERGY

Energy being consumed is to be perceived from two angles – (i) the energy required to maintain the Internet infrastructure and WWW and (ii) the energy consumed by the device using a service offered by Internet.

Energy Consumed by Internet

Physical Internet consists of 1.6 billion connected PCs and notebooks and 6 billion mobile devices (Tessel 2013). Even if energy efficiency of com-

puting has doubled every 1.5 years, the combined use of energy consumption (80% at the time of use and 20% at the time of manufacturing) is a concern. The second largest component of Internet is the data centers. Data centers are the cloud infrastructure of the Internet used by the service providers to maintain the web servers and data. Estimates reveal that assuming low power cost a typical data center costs roughly \$7 million per megawatt to build, and \$9 million per megawatt for the cost of electricity (Mills, 2013). For instance, Google's data centers use 260 million watts - enough to power a city of 100,000 to 200,000 people (Daily Mirror, 2011). It is estimated that the Internet uses 84 to 143 gigawatts of electricity every year, which amounts to between 3.6 and 6.2 percent of all electricity worldwide (Jonathan, 2012) (Michael, 2014).

There are two perspectives of the energy consumed by the Internet. One is that considering the mammoth amount of the total energy consumed by the Internet and the global energy challenges, the energy consumed by the Internet is significant. The other perspective is that it is consuming only about a small fraction of the total—between 1.1% and 1.9% of the 16 TW used by humanity (Barath & Justin, 2011). The objective of this chapter is to consider how energy can be conserved from the point of view of end users and service providers, however small may be the contribution made by these conservation measures.

Energy Consumed by Devices When They Use Internet Services

This discussion can be sub divided into two categories: (i) energy consumed by the devices when they use Internet, and (ii) energy consumption by the Internet while a device makes use of an Internet service.

Energy Consumed by the Devices When They Use Internet

Several studies are available assessing the energy consumed by a device while it accesses a service offered by Internet. It is clear that considerable

time is spent by a user in getting connected with the Internet and naturally a browser will be one of the software that will be in use for the majority of these sessions. Studies reveal that the Internet browsers increased energy consumption by about 7% to 13% for notebooks and 3% to 5% for desktops. HTML 5 websites with flash videos also increased the power consumption considerably (Kurt, Shreyas & James, 2013). Energy consumed by the components of web pages such as images, client side scripts and cascading style sheets (CSS) also contribute to the net energy consumed by the machine. It is found that the amount of energy used to render images is proportional to the number and size of images on the page. For instance 24.22% of the total energy to render the YouTube page is spent on images, as there are 5 large images representing a screenshot from each video. Gmail, in contrast, take only 6.86% total energy as it contains only small GIFs (13 pixels wide) and images. Rendering energy needed to process the JavaScript also contribute to the energy consumption. Amazon (with a large complex script, which is to be downloaded to the users' devices when accessed by them) consumes 16.89% of its rendering energy for handling JavaScript. Yahoo's JavaScript code (amount of code is less, but the code is executed every time the page loads) processing takes only 6.79% of the total rendering energy. The rendering cost of CSS depends on the number of items styled using CSS. Amazon (with 104 items to be styled, complex styling in the page like a color fade out effect, horizontal bars to show product ratings, and huge wide buttons) has a high CSS rendering cost (17.57%) compared to a 3% of the total rendering energy cost for Gmail (simple styling, small size and defined in an internal style sheet) (Narendran, Gaurav, Angela, Dan, & Jatinder, 2014).

There are hidden energy costs when websites with advertisements are browsed. The energy consumption will have to be done by the client machine. It is found that online advertisements are highly CPU – intensive, even if they consume only a small space on the page. It is found that (i)

energy consumption is increased by 12% when websites with advertisements are browsed, (ii) when number of open tabs are more, more energy is consumed, (iii) both Apple Safari and Microsoft Internet Explorer 8 seem to require more energy than Firefox, and (iv) the total energy used for displaying web advertisements is equivalent to the total yearly electric energy consumption of 1891 Dutch households (Simons & Pras, 2013).

Internet connection devices like modems and routers also contribute a lot to the power consumption. It is estimated that in US, these devices consume 8.3 billion kilowatt-hours a year (Jonathan, 2012).

Energy Consumption by the Internet While a Device Makes Use of an Internet Service

When a device is hooked to Internet to avail a service, lot of energy consumptions are done by the Internet infrastructure, in addition to the power consumed by the device itself. Estimates revealed that per second spending of browsing a simple web site resulted in the generation of 20 mg of CO₂. Demand for data by the users is also getting increased – it is predicted that average demand for data for each person will be 32GB of data per day – 2,570 exabytes (1018 bytes) per year for the global population. The average power needed to sustain such activity would be 1175 gigawatts, equivalent of 1,175 large coal-red power plants (Ruzena, 2013).

When a search is made to access a desired page in WWW, considerable energy is consumed by the data centers to provide us the answer. For instance, each Google query has to travel on average 1,500 miles to a data center and back to return the answer to the user (Mitchell, 2012). Estimates done by the Google reveal that 100 searches on google.com uses equal power to light a 60 watt bulb for 28 minutes (Daily Mirror, 2011). Estimates reveal that Google spends about 0.0003kWh of energy on an average search query, translating to roughly 0.2g of carbon dioxide – hence one Google search

is equal to turning on a 60W light bulb for 17 seconds (Jared, 2011).

Email messages contribute a lot to the global energy consumption. An Email of 1 MB would result in the emission of 19 grams of CO₂. When the message is copied (cc'd) to 10 people, its impact is 73 grams of CO₂. Emails with attachments make energy consumption still worse – an e-mail attachment of 4.7 megabytes (MB) creates as much greenhouse gas as boiling a tea-kettle 17.5 times. This is due to the fact that when an email is sent it has to be maintained in the data centers and it is read/downloaded by the recipients concerned. It is found that in a 100-people company where each employee sends on average 33 e-mails a day and receives 58, the greenhouse gas emission linked to emails would be around 13.6 tons of CO₂ per year. If there is a 10% reduction in the Email for such a company, they would save CO₂ emissions equivalent to one round-trip flight between Paris and New York (Balasubramanian D., 2011) (Vita, 2011).

Apart from transmission of Email, tasks such as maintenance of Inboxes, handling of proper mails and sorting of spam mails also contribute to the carbon emissions. The energy consumed increases when the Email Inbox contains more number of mails. It is estimated that 80% of this electricity is consumed by the reading and deleting of spam and the identifying genuine emails that that ended up in the spam folder accidentally. The carbon footprint of a genuine email, spam email and an email with an attachment is estimated as 4g, 0.3g and 50g of CO₂ emissions, respectively (Mike & Duncan, 2010).

When the frequency of updations done thru social media sites are also considered, it can be seen that the per minute energy consumption and subsequent carbon emissions caused is quite alarming. It is found that three days of streaming YouTube video requires as much energy as making, packaging and delivering a DVD (Daily Mirror, 2011). Keeping in mind the energy requirements for email service, one can assume the energy consumption required to maintain social media sites.

For instance, in 2013 Facebook's carbon footprint per person on the site was 0.000311 metric tons of CO₂ and the total power consumed was 822M kWh (Carbone, 2010). The energy consumed in transmitting 1GB of data is estimated to be 19kW - considering the huge number of images that are shared through social media sites, net energy consumption due to this also become considerably large (Bryan, 2013). Hence it can be concluded that the requirements of for power is getting increased day by day, due to the wide popularity of Internet usage.

FUTURE RESEARCH DIRECTIONS

The demand for increased energy requirements in the era of ubiquitous computing and subsequent carbon emissions pose several challenges to the research community. A multifarious attempt is to be carried out both from the perspective of users and service providers in this regard: (i) even if the energy consumption statistics of search giants like Google look alarming, these companies are investing heavily in the generation of renewable energy sources. Considerable efforts are to be done to make the technology for renewable energy cost effective and viable, (ii) regarding the power requirements of wireless mobile devices, constant efforts are required to pack more energy to the limited size of battery – nanotechnology, biocomputing and computing using light may provide reprieve to these issues, (iii) search algorithms are to be fine tuned to provide the exact reply to the query being provided by the users, so that the user is tend to end up the query with the first attempt of the search itself, (iv) efforts to minimize the size of text messages and images without compromising the quality of the content is to be addressed, (v) energy aware methodologies in the web page development for desktop and mobile devices separately, and (v) efforts in developing components for computers and networks that consume less energy (Balasubramanian, 2011) (Narendran *et. al.*, 2014) (Ruzena 2013). It is

worth mentioning that several works are already reported in this regard. A detailed survey listing the contributions made so far is outside the scope of this chapter, hence it is not discussed.

Browsers have to be more power aware when dealing with the issues such as handling client side script, CSS and images.

From the user's side an awareness is to be generated among them to point out that everything won't go green when one goes for online services: (i) the memory space in the computer is to be freed regularly, (ii) e-mail boxes (in and out mails) are to be cleaned periodically, (iii) the number of recipients for each e-mail are to be limited, (iv) reducing the size of the attachments (boil less tea- water) and uploads, (v) entering the URL address directly rather than use a search engine for every access to the same website, (vi) don't leave computer and accessories on overnight (as many offices do), not even on 'sleep mode' (even if that eats up only 1-10 watts), laptops use 15-60 watts while desktops use 250W, (viii) reduce the power by doing more 'offline' work than online, and (ix) remember Facebooking and Twittering burn carbon and make CO₂ (Balasubramanian D., 2011) (Narendran T., Gaurav A., Angela N., Dan B., and Jatinder P. S., 2014) (Ruzena C., 2013). Users have to a judicious use of these blessings – only when needed, in the right context and in the appropriate measure.

CONCLUSION

Easy availability and affordability of devices and accessibility to wireless networks, there is an exponential growth in the number of devices in use. Popularity of feature rich mobile devices that can be hooked to the wireless networks among the users all over the world resulted in vanishing the barriers of locality and time – as far as computing is concerned. This gave birth to an era of computing known as ubiquitous computing.

Ubiquitous computing and availability of Internet is just revolutionizing the way people make

use of computing devices. Predications revealed that the monthly global mobile data traffic will surpass 15 exabytes by 2018. Popularity of mobile devices and increased use of Internet poses several issues and challenges to the research fraternity. One of the challenges is the energy consumption by the devices and the Internet backbone.

Energy consumed is to be perceived from two angles – consumption by the Internet infrastructure and devices being connected to the Internet by the users. It is found that Internet infrastructure uses 84 to 143 gigawatts of electricity every year, which amounts to between 3.6 and 6.2 percent of all electricity worldwide. Every activity on the Internet such as getting search results from search engines (Google processes over 40,000 search queries every second on average - 1.2 trillion searches per year), sending emails (200 million emails every minute), engaging in social media websites (number of postings made by the users on Facebook reached nearly 2.5 million, contents uploaded to YouTube amounts to 72 hours of content, and Instagram users share 216,000 new photos per minute) consumes considerable amount of energy (100 searches on google.com uses equal power to light a 60 watt bulb for 28 minutes, emails with attachment of 4.7 megabytes creates as much greenhouse gas as boiling a tea-kettle 17.5 times, for instance). In addition, the devices also consume energy while they are in use.

The growing energy consumption and the attempts to conserve energy poses several challenges to the research community such as (i) renewable energy is to be made cost effective and viable, (ii) more energy is to be packed to the limited size of battery space, especially on a mobile device – technologies such as nanotechnology, bio-computing and computing using light may provide efficient solutions, (iii) search algorithms are to be fine tuned to provide the exact reply to the query being provided by the users, so that the user is tend to end up the query with the first attempt of the search itself, (iv) size of messages (text, images, audio and video) are to be minimized without compromising the quality of the content, (v) design

of energy aware methodologies for developing web pages for desktop and mobile devices separately, and (v) efforts in developing components for computers and networks that consume less energy. Conscious efforts should be made from the users' part also to reduce the energy consumption by at least limiting the use of technology considering need, necessity and priority.

This work is indented to bring forth the issues and challenges in the area of energy consumption in the era of ubiquitous computing. A detailed study is to be undertaken to assess the progress of the works being reported in the energy conservation measures – this will help one to understand the state of the art and frame new solutions and approach. This is left as the future work.

INTRODUCTION

The choice, development and use of technologies has very varied impacts on the progress of human beings and nature. In some cases, this impact leads to a radical change in the context of users of a specific technology, both in social and cultural terms. This technological innovation or invention is labelled enabling technology and is mainly characterized by the rapid development of subsequent technologies, often present in several scientific and social fields.

In this sense, ubiquitous computing, pervasive technology and smart spaces represent enabling technologies which have conditioned the evolution of the current Information Society (IS). These ICT boosting the development of Internet of Things (IoT), wearable sensing, Cloud Computing, Smart Textiles, etc., which are transforming society and particularly changing the interfacing methods between services and user as well as their expectations from services. Such changes are related to arising of new kind of pervasive and sensitive service such as new healthcare and well-being personalized services or the final irruption of the Smart Home.

In this article such kind of services are defined in a comprehensive manner including their general objective, limitations, potential interrelationship,

etc., including the supporting literature and reported related work but not limited to a mere review of the available literature. This sense, sensitive services refers to new IS services that manage data that is not only based on the physical disposition of the user in regards to the environment (such as geographical position, interior positioning, or patterns of movement) but also related to more personal aspects of their physical state, psyche, or behavior patterns. On its part, pervasive services are those developed by using pervasive technology such as cloud computing, Internet of Things approaches and therefore can be defined as a delocalized and persistent ICT service that allows its users to access the functionalities it offers at any time or place. These definitions will be supported by an analysis of the evolution of services of the IS both from a socio-economic and industrial focus.

BACKGROUND

The IS refers to the social model in which the means of wealth generation are based on the production, management and transmission of information (Sarell & Machlup, 1963). In the IS, information and knowledge are established as the main economic engine, giving greater importance to services over production and products. Infor-

mation and knowledge technologies (ICT) are an essential tool for the development of IS services. Their main objectives are the generation of knowledge and the exchange of information, through its encapsulation in the form of services to ensure its efficiency and accessibility to the citizen.

The services deployed in this society have undergone a continuous evolution to adapt to the needs of society and the specific characteristics of the technology used for its development. The incidence of these services in the IS goes beyond the technical field, and its evolution has been influenced, not only by the technology used in its development, but also by the socio-economic factors related to new forms of communication and global coexistence.

In (Achrol & Kotler, 2014) services are defined as the application of specialized competence by an entity through actions, processes and activities for the benefit of another entity or the own. This concept, in the context of the IS, refers to any set of features provided at a distance, electronically and by individual request from the recipient of the service (Directive 98/48/EC of the European Parliament and of the Council). To achieve this, ICTs are used as a means of developing the transmission, processing, and storage of the data associated with it.

In contrast to a specific product, the services deployed in the IS are specified at the time they are required by the user. The specifications or design requirements of the services can and must be defined a priori, but their implementation, deployment and behavior are subject to their use. This means that the services are tailored to the needs of the moment when they are required. This situation requires that the users can control and understand the elements involved in the use of the service at the time in which they are accessed, regardless of the technical complexity and underlying technology. In this way, the IS offer their users increasingly complex and useful services whose efficiency and effectiveness is subject to the relationship of communication between them. Given the complexity of nuances in many existing

services deployed, a detailed study and design of all of the elements of the service is necessary. Within these elements, the communication relationship between users and services is of particular importance for two basic reasons related to their implementation in society and the management of the inherent complexity of these services. On the one hand, the ever increasing inclusion of these services in the daily lives of people means that these affect more intimate and personal aspects of users, which could generate rejection or fears that did not exist initially. On the other hand, a more complex functionality that addresses closer needs to the user implies an increased degree of service sophistication and interconnection.

To better understand the importance of the relationships between users and the services of the IS it is necessary to analyze its evolution, from a more focused approach in the management of the information until a conception aligned with enabling technologies such as ubiquitous computing, pervasive technology or intelligent environments.

The Evolution of Services in the Information Society

As has already been mentioned, the evolution of services in the IS has been marked not only by the ICT used in its definition, but also by the needs and wants of the citizens that make up the society of the availability of the basic resources needed for its proper development.

Throughout this section, the evolution of services in the IS will be presented from two perspectives. The first analyses said evolution from a socio-economic focus in order to understand how key aspects of today's society and its needs have influenced the development of these new services in the IS. The second presents a view of the evolution of development efforts and investments made by the big ICT companies over different sectors of society in order to create new services in the IS.

Although development efforts for these services and their evolution are currently oriented

towards various areas of people's lives, book chapter is centered on two fundamental aspects, health and the intelligent home. Health and social well-being represent a group of services with an extremely high tendency to impact society and industry. Intelligent homes offer an important tool for enabling the spread of healthcare and personal wellness services.

Socio-Economic Focus

An ever-higher quality of life and an ageing population paint a picture where the number of users of health and wellness services is constantly increasing. Health assistance and wellness services play an increasingly critical role in consumer and, especially, State expenditures. This picture, along with the cyclical economic crisis situations that our society suffers from, forces States to redirect the distribution method for this type of services towards more sustainable methods in regards to time and resource use.

Enabling technologies, such as ubiquitous computing and pervasive technology, have allowed health assistance to be transferred into the daily context of users. This new paradigm of service distribution, along with the expected capacity of the Digital Home, are considered promising and more sustainable alternatives to traditional hospital-centered developments. Thus, the telehealth industry has turned into a competent complement to traditional health services and, as seen earlier, also into an opportunity for the development and distribution of new services by the ICT industry. In 2013, this industry generated US \$240 million in revenue through three primary means of care: store-and-forward, programmed real time, and emergency real time (GrowthCap, 2014). According to this, the telehealth market is about to grow to an annual cumulative rate of 56%, to \$1.9 billion in 2018. This implies that the number of patients using telehealth will grow from 250 thousand in 2013 to 3.2 million in 2018.

This evolution has created a change in vision for service development from a more complete and

complex concept to a simple and more accessible solution. In this way, the acceptance of services by users is fostered, while improving its distribution in society and, thus, its socio-economic impact. The application of mobile technologies, such as smart phones or tablets, as well as enabling technology, such as pervasive technology and ubiquitous computing, has favored the inclusion of companies that are foreign to the sector and the participation of governments as support entities.

If the expectations for telemedicine are, in fact, promising, the reality is that, up until now, the telemedical solutions distributed had achieved varying levels of success. In addition, this variability in the success of Telemedicine occurs in disparate development indexes. Even now, Telemedicine is used in a residual manner as a method for rendering routine services and only a few pilot projects have been able to sustain themselves once the development phase of the prototypes has finished.

The majority of studies related to the analysis of the true distribution of Telemedicine solutions show that patients and service providers are resistant to adopting service models that differ from the traditional focus or local practices, while others lack an ideal level of necessary knowledge and technological culture to use the new focus effectively. The most notable complex problems are related to linguistic and cultural differences between patients (particularly the underserved) and service providers (Al-Shorbaji, 2008; Craig & Patterson, 2005; Currell, Urquhart, Wainwright, & Lewis, 2010).

Another cause related to real Telemedicine service distribution is that it has not been a priority for most governments. In a 2010 global e-health study carried out by the World Health Organization (World Health Organization, 2010), only 52% of health and wellness services offered via Telemedicine had been adopted and established in countries by their governments. However, it seems that currently, governments have become more conscious of the need for this type of services. States are primarily concentrating their economic efforts on the investigation and creation of services

aimed at healthcare and wellness, including Telemedicine. In the European Union, Eurobarometer 419 (European Commission, 2014), researching European citizens' perceptions on the topics of science, research and innovation, established that the evolution of the services in the IS dedicated to the promotion and protection of health and wellness represent, along with job creation, the main priority for science and technological innovation for the next 15 years. Figure 1 shows an analysis about the priority of research and development-based on 13 basic aspects of current society and the expected positive impact of research and technology with regard to the expected impact of each citizen's individual action.

It becomes clear that current society is aware that the inclusion of ICTs to create effective and

useful services represents a necessary aspect of its development. Nonetheless, the manipulation of private and personal data performed by this type of services, together with its inclusion in the daily life of users in a pervasive manner (clothing, home, work spaces, schools), generates a certain level of rejection and fear that inhibits its complete adoption. Governmental agencies are aware of this and continue working on legislation for these sensitive services as a means of user protection since the mid-90s. As will be analyzed in the following sections, adopting this type of services is determined by the factors intervening in the development of sensitive services and how the enabling technologies presented in this chapter affect the storage and management of the information they control.

Figure 1. Comparative graph of the expected impact of science and technology and the individual actions of each citizen for the 13 most representative areas of current society's activity (European Commission, 2014)

Figure 2. Trends in seed capital investment from 2010 to 2014 in the USA (Data source: Crunchbase)

Industrial Focus

Market movement and business investing from the largest companies in the ICT arena offers an addition perspective on understanding how services in the IS have evolved over the years. Figure 2 shows investment trends by business sector in the group of all American start-ups in their creation phase from 2010 to 2014. It can be seen that the traditional sectors related to Hardware and Software development, instant messaging, education, and mobile technology maintain a high investment index. However, movement towards an increased investment in other sectors can be discerned, marking an evolutionary trend in the services in the IS. The fashion sector, covering manufacture of intelligent fabrics, among other things (Fashion), E-Commerce, Hospitality and Digital Home development (Hospitality), and sectors related to health and wellness (Healthcare and Health and Wellness) have received a larger

rate of investment since 2010, putting them on par with the traditional sectors.

Large companies such as Google, Microsoft, Apple, etc., have followed this trend. In case of Google, the services developed originally were oriented towards the need and desire of its users to share and acquire knowledge, and it was managed and organized with a powerful search engine, the symbol and brand of the company. However, during the 2010-2015 period, Google has reoriented its development and acquisition of external companies towards the study of life sciences and development of Digital Homes. As shown in Figure 3, in 2014, investments made by Google Ventures, a sub-company dedicated to the acquisition of other companies as subsidiaries of Google, exceeded 35% in the Health and Life Sciences sector, putting it above even the mobile phone sector. This trend materializes in the creation of a highly protected division, Google[X], aimed at producing major technological advances,

Figure 3. Cont. Trends in seed capital investment from 2010 to 2014 in the USA (Data source: Crunchbase)

Figure 4. Investments in 2014 by Google Ventures (The New York Times)

emphasizing its line of research and innovation in the study of life sciences.

Other relevant ICT sector companies such as Microsoft, Apple, or IBM have also evolved their developments towards a convergence with healthcare. Specifically, Microsoft created the company Avanade alongside Accenture in 2010 with the objective of covering the needs of society focusing on health and wellness. With this initiative, Microsoft's technologies such as Kinect, Skype, and HealthValue (a tool based on services on the cloud for the exchange of patients' clinical histories) are joined together. In Apple's case, the development trend for this type of sensitive services materializes in their bet on information processing in regards to health through HealthKit, available on all its new devices. Lastly, IBM has aimed its technical and technological capacities towards clinical data analysis and development of technical tools for improving the healthcare process, an idea that has been captured in the interoperability framework IBM Watson Health.

Another sector where the biggest representatives of the ICT sector have overwhelmingly decided to invest since 2010 is the development of Digital Homes. In 2014, Google acquired the companies DropCam and NestLabs, cutting-edge enterprises in the development of solutions for the Digital Home. In this way, Google attempted to turn itself into a reference source in this field through development of systems and services for the Digital Home alongside adapting and using its mobile operating system, Android. In addition, Microsoft or Apple, who in the beginning were aimed towards the development of tools for knowledge processing or communications, have seen the opportunity that the Digital Home offers. In this way, new systems and technological developments aimed at this sector have appeared, such as HomeOs (Microsoft Research), an ad-hoc operating system aimed at device management, communication frameworks for Digital Home elements such as HomeKit (Apple Inc.), AllJoyn (Linux Foundation), and Thinking Things (Tele-

fónica), or research and development divisions such as Lab-of-Things (Microsoft). Amazon has also jump onto the Digital Home bandwagon with Echo, a coordinating device for home device networking and direct communication between the user and the Digital Home. As such, this means an important bet from the big ICT companies on the development of this technology that transforms the user's most private and personal spaces. Conscious of the business advantages and development possibilities that the Digital Home offers, they have decided to broaden their fields of business to all levels of the Digital Home, from a purely physical level with sensor and actuator development to a functional and logical level, represented by operating systems and interoperability, communication, and implementation platforms.

As observed in the development of investments by the big ICT sector and IS companies, the development of services for user health management and wellness and the transformation of the home into an intelligent platform for distribution of services represents a field of development with a wide margin of benefits, both economic and social (Balta-Ozkan, Boteler, & Amerighi, 2014; Martin, Kelly, Kernohan, McCreight, & Nugent, 2008). One of the most important implications of this shift is the emergence of two new types of services in the IS: sensitive services and pervasive services. In the following sections a clear and concise definition for both is offered.

SENSITIVE SERVICES

The evolution analyzed in the previous section shows a design and development trend towards services with a greater social impact in terms of quality of life. In addition, technologies giving shape to those services with a greater degree of autonomy, ubiquity, delocalization, and control over their users' personal aspects are evolving in parallel.

These new services manage data that is not only based on the physical disposition of the user in regards to the environment (such as geographical position, interior positioning, or patterns of movement) but also related to more personal aspects of their physical state, psyche, or behavior patterns (Ackerman, 2013).

More and more studies show the difficulties related to services that manage data or situations that are considered personal or of special importance to the user. In this sense, a sensitive service will be formally understood in this article as a service that fulfils the following conditions:

- The combination of its functionalities significantly affect its users' quality of life;
- It manages information that is considered private by its users. This information may be provided by users or service providers, learned via automations, or inferred via data mining processes;
- It involves the psychological responses of its users, being able to condition its own behavior or activities;
- They are present in the users' personal spaces, such as the home, school, or workplace, and as such affect the development of day-to-day activities.

Another defining trait of this type of service is where it is to be implemented. They not only affect their users' personal data, but also must be implemented in living spaces where daily life unfolds, such as the home, school, hospitals, or workplaces. Bettini & Rinobi propose, in (Bettini & Riboni, 2015), a classification of personal and sensitive data according to the category of the sensitive services provided. In this sense, for example, a health service deployed in the Digital Home, for its proper functioning, must record and analyze user activities in such an intimate and personal space as is the home. This represents a clear example of a sensitive service that fulfils

the requirements for a sensitive service that were previously expressed.

PERVASIVE SERVICES

The consolidation of the Internet as a means of communication in the IS has encouraged the evolution of computing systems from a centralized concept towards a viewpoint based on a shared information network where all users store and execute services. This situation is commonly known as Cloud Computing. Additionally, advances in the miniaturization of technological components linked to computing has enabled them to be embedded in everyday objects, creating computing networks based on common objects. This phenomenon is known as the Internet of Things (IoT).

These advances have also affected the development of IS services. At one point, these services were offered as a complex element that involved a higher level of control from their users. Currently, these services are offered by operators as simple functionality packets in objects that are already utilized and known by users such mobile phones, electrical appliances, furniture, etc. The orchestration of the capacities offered by these objects with computational capacity and the possibility of remotely processing information has contributed to the appearance of new ICT services called pervasive services. This way, *a pervasive service will be defined as a delocalized and persistent ICT service that allows its users to access the functionalities it offers at any time or place.* The delocalization of these services and their accessibility via the Internet independent of the user's location has facilitated their inclusion in individuals' daily life, thus offering more personalized ICT services. This simpler, delocalized, and persistent IS service concept promotes access by all users, independent of their location, technological culture and knowledge, social condition, or purchasing power.

ISSUES OF THE NEW SERVICES IN THE INFORMATION SOCIETY

Despite the fact that the number of laws and regulations directed at creating privacy and protection for users of this type of sensitive and pervasive services (i.e. the European Data Protection Supervisor (EDPS) or In the Health and Human Services (HHS) in USA) has grown over the last 20 years, the perception of control from the citizen's perspective has deteriorated. According to Eurobarometer 431 (European Commission, 2015), from 2010, researching Information Protection, it can be seen that only 15% of the European population believes that they have total control over data shared when using services in the IS. On the other hand, 31% of the population believes that they do not exercise any control over this information and finally, 50% believes that they exercise some control over shared data while using services in the IS.

A comparative analysis of the results offered by the 2015 Eurobarometer with the one created in 2010 show that the feeling of control over this data has varied. In 2010, the users of these services had a greater perception of control over data than in 2015. While in 2010, only 20% of users believed they did not exercise any control over information, in 2015 it increased by 12%, decreasing the percentage of users that were confident in their control over shared sensitive information. However, these users show a greater awareness, in comparison with the 2010 results, of daily activity monitoring with the use of IS services.

This shows that the sensitivity of the data managed by these services has increased, in large part because these services are more present in users' daily life. Citizens are more and more aware of the existence of risks related to the use of this specific type of services. These risks include fears that impede the acceptance of a technological solution and encourage its rejection in the presence of a viable alternative (Khadke & Chavan, 2014; Weiser, 1995).

In the other hand, the use of pervasive technology for the implementation the new services in the IS and their delocalized nature foster a state of rejection towards the information managed, generating insecurities about who manages such information and how. A study carried out by the CloudT project among European (Spain, France, and Italy) and Japanese entities, whose goal was to boost citizen influence in a future concept of an intelligent city, shows a global viewpoint on citizens' familiarity with the concepts of Cloud Computing and Internet of Things. While the Cloud Computing concept seems to be better-understood by society with 24% positive responses, the IoT turns out to be familiar for only 15% of the surveyed population. That means that 60% of the population is unaware of the nature and objectives of this type of technology, affecting final adoption of the services constructed with it.

FUTURE RESEARCH DIRECTIONS

The main future research arising from this work is the study of acceptance of pervasive and sensitive services. A deep analysis of how the acceptance affects the final adoption of these services is beyond the scope of this paper, however, the authors of this paper believe that this study represents a line of future research of utmost importance. In this sense authors have conducted several researches that provide different analysis approaches for this future line of work, establishing key indicators that can be used to model such acceptance (Vega-Barbas, Pau & Seoane, 2014).

Another line of future work related to this work is the development of systems for the visualization of complex data. Visualization represents an important means of communication between users and systems. No longer just to display complex data in a way that is understandable, but also to expedite the process of interaction with smart spaces and pervasive services. The rise of the deployment of Smart Cities means that the possibilities offered

to users grow uncontrollably. This situation can overwhelm users, preventing proper adoption as valid solutions.

CONCLUSION

The evolution of the IS has been marked by a shift of importance where services have supplanted almost entirely to specific products. As with traditional products, the services are conditioned by the underlying technology used for its development and definition. However, new needs and desires of society have acquired a vital importance in the evolution of these services, giving rise to two new concepts, services and Pervasive sensitive services. Although these concepts are present in industry and academia there is no clear definition. In this sense, this article provides a definition for both concepts with the aim of being used as a means of understanding and adapting to the new challenges that the IS must face. In addition, along of this article the main problems and challenges that these services must meet to be used as a means of developing good solutions have been highlighted. Thus, technology acceptance is presented as the main challenge associated with these new services, which must be adapted to new technological and socio-economic paradigms on which such services are developed.

KEY TERMS AND DEFINITIONS

Enabling Technology: Technological innovation or invention which is mainly characterized by the rapid development of subsequent technologies, often present in several scientific and social fields.

Interaction Design: An interdisciplinary vision that is fundamental to all disciplines, fields, or study and development approaches whose objective is to create systems based on computing technology for individuals such as Human-Computer Interaction, Ergonomics, Human Factors, Cognitive Engineering, Psychology or Design.

Pervasive Service: A delocalized and persistent ICT service that allows its users to access the functionalities it offers at any time or place.

Pervasive Technology: Potentially ideal environment, due to its characteristics, to support Ubiquitous Computing which fundamental characteristics are resilience and persistence.

Sensitive Service: An ICT service which as combination of its functionalities significantly affect its users' quality of life, manages information that is considered private by its users, involves the psychological responses of its users and are present in the users' personal spaces.

Technological Acceptance: Degree of adoption and use by the user of goods or services as the practical application of knowledge, whose objective is to satisfy a need or want of society.

Ubiquitous Computing: The third computing paradigm where the person relates physically with a large number of computers without temporal or spatial restrictions.

INTRODUCTION

At the third computing era, users interact with many computing devices surrounding or implanted in them, in a natural way. These anytime and anywhere interactions implement the concept of *ubiquitous computing*, which provides the framework for computational awareness and personalization. These properties are precious in healthcare applications since the operating computing devices in the patient's environment can be aware about the evolving situations and actively participate in the medical treatment. In addition, ubiquitously supported healthcare services can be provided anywhere and at any time, allowing specific cases of the hospitalization model to be transferred to the home healthcare model.

The adoption of the home healthcare model in a ubiquitous computing environment provides the prerequisites for the development of the presented *Home UbiHealth* model. Extending medical services at home provides the capability to cover the medical needs of all population categories. Specifically, the Home UbiHealth model refers to all major population groups, namely the healthy population supported with prolepsis policies that retain health status; individuals that suffer a health crisis that requires recovery; and chronic patients who must maintain their quality of life coping with known health problems. Within the above

patient categories are included the special groups of infants, children, disabled, and pregnant, which have special healthcare needs.

Thus, the home environment is transformed to a reference starting point for the implementation of healthcare processes independently of location and time, thereby bringing together the various healthcare stakeholders and the market. In this framework, the Home UbiHealth model can change the perception about the structure of healthcare systems and the concerns about medically uncontrollable environments.

BACKGROUND

In recent years, medical research has offered tremendous developments. Within this framework, specialized personnel is required to carry out advanced processes within properly structured and controllable facilities, using state-of-the-art biomedical equipment. Unfortunately, the availability of medical resources hardly meets the current social demands for hospitalization in cities and rural areas. This is partially due to the long average hospitalization periods required to perform trivial medical and nursing procedures such as screenings, lab-tests, or follow-ups. The lack of adequate infrastructures leads to longer stay of the patient in hospital.

DOI: 10.4018/978-1-5225-2255-3.ch675

These deficiencies can be addressed through new healthcare models that are supported by modern computing technologies such as ubiquitous computing. Ubiquitous computing was introduced by Mark Weiser to describe the *third wave* or *calm computing* (Weiser, Gold & Brown, 1999), where computers are enweaved into every fabric supporting the end user. In this era, the users are supposed to subconsciously interact with many computers, concurrently, in such a natural way as one uses eye-glasses to restore vision problems.

The application of ubiquitous computing in healthcare systems introduced the term *ubiquitous health* (*UbiHealth*) to describe the use of inherited computing characteristics in healthcare models (Sarivougioukas & Vagelatos, 2015). UbiHealth refers to healthcare services that incorporate ubiquitous computing means. Such services can provide critical advantages to overcome limitations related to individualized care, medical personalized treatment, patient safety, economy of scale, as well as healthcare system efficiency, effectiveness, security, and scalability.

Controllable hospitalization is directly related to quality of treatment, continuity of care services, transparency of medical and nursing supportive activities, patient safety, and administration of the involved supply-chains and related costs. In principle, UbiHealth satisfies the requirements related to the quality of the provided medical and nursing services, the demands for continuity of the involved processes, the necessary conditions of transparency in the followed procedures, and the fundamental prerequisite of safety for medical professionals and patients. Hence, UbiHealth can highly contribute to overcome issues related to hospitalization by providing the ground for medical and nursing processes within ubiquitously performing environments, such as at home.

Treating and curing patients at home (see Figure 1) has been considered as beneficial for particular population groups and has been extensively tested (Madaris et al., 2016) to the point where the treatment is under complete control by the assigned medical personnel. Usually, this

refers to post-acute care or chronic patient cases. A typical example is the *Medical Home* paradigm (American Academy of Pediatrics, 1992), which was introduced by pediatricians to control infant mortality and children vaccination.

The significance of home treatment has been verified with respect to prolepsis, prognosis, testing, cure, and treatment. However, the continuously increasing costs of advanced cures, which are habitually applied in highly specialized facilities by specialized medical personnel, has turned the interest of the scientific community to home-based alternatives in order to address the lack of adequate treatment resources. Moreover, the associated risks during hospitalization, such as nosocomial internal infections, accidents, medical mistakes, and human errors, motivate researchers to delve into solutions alternative to hospitalization.

In addition, the bureaucracy imposed by long hospitalization increases the complexity of the carried processes, resulting in significant time and cost growth. In turn, this imposes substantial overhead to social security services, insurance funds, and the related market. Furthermore, limited available hospital resources are incapable to offer individualization of the provided services due to the applying workload. This is in contrast to the endeavors of medical practitioners and healthcare systems, which aim at personalization in the of-

Figure 1. Home Care main components and their relationships

ferred cures according to the patient needs and preferences (Snowdon, Scnarr & Alessi, 2014). Home UbiHealth offers a promising solution to this problem, given an adequate ubiquitous health ecosystem.

HOME UBIHEALTH ECOSYSTEM

Home UbiHealth systems operate in an environment where evolving compound processes follow complex workflows that involve stakeholders with diverging concerns and interests. The Home UbiHealth environment includes an underlying computing infrastructure that supports the patient's personal healthcare needs along with interaction with all participating stakeholders. Hence, Home UbiHealth can be considered as the common loci where computing and healthcare support personalized healthcare needs at home, eliminating time and space limitations.

The available technological developments provide the opportunity to resolve several issues in Home UbiHealth, which are related to three major problem areas. The first area is related to the lack of standardization in the home computing hardware infrastructure. This is tackled with the introduction of the *Internet of Things* (IoT), which allows overcoming problems such as the ones in local area networks applications (Riggins & Wamba, 2015). The second area is related to software infrastructures. This is addressed through *cloud computing*, which provides a variety of schemes such as software as a service (SaaS), platform as a service (PaaS), and infrastructure as a service (IaaS) (Ullrich, Vasileiadoy & Tamm, 2011). The third problem area is related to configurability that is necessary to address medical and social issues. This is handled by properties of ubiquitous computing such as the *computing awareness*. Thus, despite the raised problems, there is a variety of technological tools available to support the implementation of the Home UbiHealth paradigm.

The Home UbiHealth model aims at conditionally substituting parts of hospitalization (Leff, 2015), provided that prescribed prerequisites are fulfilled. Although the physical presence of medical professionals is irreplaceable, there are specific procedures that can be carried out in reformed fashion, assisted by computers and communication equipment. This can reduce dependability from specialized professionals. The Home UbiHealth model aims at sharing scarce medical resources by employing reliable and effective communication schemes. However, it may suffer from intolerable commuting overheads (Leff, 2009) since the supporting professionals are obliged to pay scheduled visits at patients' place.

The presence of medical professionals at home to consult family members and caregivers has a twofold purpose. First, the doctor at home audits and instructs about the appropriateness of treatment activities. Second, he coordinates all treatment activities regarding the in-house and out-of-house services. Therefore, the Home UbiHealth model relies on the cooperation and participation of the medical professionals, coordinated by an assigned medical doctor who determines the associated supporting services.

Medical treatment at home requires the availability of medical devices, consumables, and drugs. Also, the medical treatment involves approvals and reimbursements from social security organizations or insurance funds (see Figure 1). These procedures frequently produce delays, frustration, and significant overhead. However, the deficiencies can be eliminated through ubiquitous computing procedures. Additionally, by carrying ubiquitously performed processes, the necessary products, goods, drugs, and services can be organized on behalf of the patient, since all participating stakeholders are aware about the patient and the coverable treatment needs. Hence, multiple procedures can be concurrently activated involving all relevant stakeholders in order to meet the needs of the patient at home.

For instance, a doctor's prescription can receive the necessary approvals from the sup-

porting insurance fund, be executed by the local pharmacy store, and delivered at the patient's home. Therefore, the Home UbiHealth model can become a reference point for ubiquitously performed healthcare processes on behalf of the patient with minimal bureaucratic overheads and complete approval control.

DESIGN PRINCIPAL PRIMITIVES

The implementation of the Home UbiHealth model requires adequate computing infrastructure, capability to achieve continuity of care, and ability to adjust the functional performance of the designed system in order to meet personal needs and preferences.

The context in the Home UbiHealth model is produced from signals of dispersed sensors and computer-controlled devices in the patient's environment. These signals form the holding *situational context*. The devices form ad-hoc cooperative communication networks that support the patient's activities. They fall into three main categories with respect to their location or mobility, namely they can be stationary, mobile or carrying, and implanted (Latre *et al.*, 2011). Major issues of the devices are related to their participation in cooperative networks and their power supply. The formed networks must follow protocols that guarantee patient's safety, security, and privacy, along with support of the patient's medical treatment and personal preferences.

Thus, the computing infrastructure is distinguished into *in-house* and *out-of-house infrastructures*. These are characterized by scalability, which is offered by the ubiquitous computing abstraction of services (Loeser *et al.*, 2003). Both infrastructures are supported by IoT and cloud reproductions, ensuring continuous and uninterrupted feeding of data over the internet. The infrastructure facilitates pre-processing, processing, cognitive, and controlling phases. The pre-processing phase involves the operations of data cleansing, normalization, fuzzification, fusion, and correlation, which ex-

clude inaccuracies, ambiguities, and uncertainties from the obtained raw data. The processed raw data is adequate for the development of the situationally holding context, after the examination of existing relations among the obtained data through rule-based systems (Sarivougioukas & Vagelatos, 2014).

Then, the processing phase applies medical rules on the obtained context in order to produce useful information. The cognitive phase correlates information supported by medical knowledge representations, such as specialized medical taxonomies, in order to draw conclusions and develop a conceptual or knowledge model. Eventually, the controlling phase operates on networks of concepts, assisted by a decision-support system that makes decisions about the proper guidance of physical devices in the patient's environment. Therefore, the computing infrastructure analyzes and processes raw data from the surrounding sensors and returns particular data to each actuating device, thereby supporting the patient without requiring direct coupling between sensors and actuating devices.

Medical doctors can determine the objectives of the cure by prescribing, ordering, and instructing the individual patient's treatment activities through dedicated user interfaces. Thus, the treatment plan is scheduled along with the necessary procedures, within and outside of home. The involved nurses and caregivers receive specific instructions about the personalized treatment, allowing doctors to be regularly informed about the treatment progress, including alarms and warnings.

The model's software infrastructure is the reference or initiation point for all processes regarding the patient's support. Besides the direct support provided by the dispersed devices within the home environment, the patient's support requires the initiation of processes as instructed either by the doctor in charge or the patient's health conditions. For instance, the order of drugs for a chronic disease such as diabetes can be activated by one of the watching medical rules on behalf of the patient, requesting doctor's approval and

placing the order to a predetermined pharmacy store according to a predetermined payment type. The performing processes are circular, starting from the UbiHealth software infrastructure and ending, upon completion, to the same system. Thus, the supporting software infrastructure can involve all necessary stakeholders for the patient's support, following workflows that bring together medical authorities, government agencies, as well as services and products from the market. The entire operation of the Home UbiHealth model depends on the availability of the internet and the capability of the software infrastructure to operate from the residing virtual cyberspace.

The autonomy of the Home UbiHealth model depends on instructions and orders provided by the medical doctor in charge. In other words, it depends on the availability of information upon which, decisions can be made. The model can be used equally well for all three distinct cases of individuals, namely the healthy ones, individuals undergoing a health crisis, and the ones with a chronic disease. The Home UbiHealth paradigm allows doctors to perform remote audits besides the necessary in-person clinical examinations. Thus, the entire health history (healthcare records) of the individual is available for consultation by the assigned medical doctor with updated, reliable, and accurate data. Also, the use of the internet as the underlying communication medium that connects the patient with the software infrastructure that resides at the cloud, provides a uniformly and continuously available reference to the personal health data. Hence, the continuity of care is achieved with respect to documentation, time, and space.

On the other hand, continuity of care in the Home UbiHealth model depends on the participation of the involved stakeholders during health-related events. The development of systems and adequate software applications motivates stakeholders to contribute to the patient's treatment. Also, hospitals can share data and continue providing support to the patient who is transferred for recovery at home. The involved

social security organizations can support the home treatment of the patient by satisfying the financial issues on-time. Similarly, suppliers of medical products, consumables, and services can be proactively prepared, avoiding bureaucratic procedures regarding the administration, financing, and supply-chain support.

Therefore, the Home UbiHealth model possesses all the necessary properties that allow the patient's support at home in a holistic manner. It can be considered as the structural cell for building healthcare systems. Its parameters can be adjusted to match the desired conditions of an efficient healthcare system with respect to public health, social needs, environmental requirements, and financial constraints. The sustainable healthcare models meet operational requirements that satisfy individual medical needs at desirable level of quality. The operational requirements are satisfied by the prompt availability of data and information regarding the patient's personalized needs, while medical needs are satisfied through the provision of services of predefined quality. Given the desired policies, aimed purposes, operational objectives, and quality level of the offered products and services, the Home UbiHealth model can be optimized with respect to its parameters. This way, it promotes the development of optimal and sustainable designs.

CHALLENGING ISSUES

Contemporary research and development efforts on the extension of the Home UbiHealth model are focused on a number of challenging issues. First, the Home UbiHealth model relies on raw data that is transformed into medical knowledge to serve the medical needs of the supported patient. Second, the provision of services must be adjusted to support personalized medical needs of the patient. Third, the autonomy of the model is determined by the availability of information upon which, decisions are made. This underlines the need for adequately designed decision-making

systems. Fourth, the Home UbiHealth model requires efficient methodologies for its formal description. Finally, the design of the model must properly address all security issues. Significant research efforts are paid on the foundations of the model's building blocks that will eventually lead to *in vivo* applications.

The medical support of patients at home requires the adoption of medical knowledge, which must be adequately represented in order to be processed and properly applied. Knowledge is obtained from the available information as a result of processing raw data provided by dispersed devices and smart objects in the ubiquitous computing home environment. The applied data transformations must be accompanied by well-structured and formally defined ontologies. These make available the current level of medical knowledge in various forms, such as rule-based systems, case-based systems, and adapted medical protocols.

The performed data transformations are affected by the patient's characteristics and personalized needs. The ontological support provides the ability to perform inferences and eventually extract the involved discrete medical concepts from the obtained information. Ongoing research efforts try to achieve such representations of the medical knowledge that can be composed from raw data in order to make decisions and, then, be decomposed into low-level data to control the dispersed actuating devices in the ubiquitous computing home environment (Sarivougioukas & Vagelatos, 2015).

Moreover, the Home UbiHealth model has additional inherent restrictions, presented below in decreasing order of significance (Teijeiro *et al.*, 2013). The first and most significant source of constraints refers to the applied medical rules that govern the decision-making components of the model. The second source of constraints refers to the introduced instructions and orders placed by the treating medical doctor, taking into consideration the particular physical and medical characteristics of the patient. The third source

of restrictions is about the personal preferences declared by the patient. Current research efforts are focused on the accomplishment of formally defined uniform representations of constraints that nest the aforementioned sources of restrictions and eliminate conflicts and contradictions (Sarivougioukas, Vagelatos & Lagaris, 2015).

Another significant issue is the autonomy of the Home UbiHealth model, which depends on the availability of decision-making components (mechanisms). Decisions are the outcomes of processing operations that take into consideration the available options. The procedural processing in decision making proposed by Simon (Simon, 1979) approximates the practical limits. However, Simon's model requires restructuring since the identification of the problem upon which, a decision is pending, must be provided by the supporting ontology. Also, the process that provides the appropriate medical decision must be proactively available by the model, in order to minimize the necessary search time.

Thus, the model must be dedicated to synthesize actions and bridge the gap between the medically suggested solution and holding conditions. Also, it must be properly designed to provide either decision-making support to the medical professionals or decision making to follow the issued orders of the prescribing doctors. In other words, the decision-making component must follow and participate in the medically adapted workflow of operations carried by the patient and the assigned doctor. Therefore, the decision-making component must be designed to take advantage of the cognition effectiveness, efficiency of intelligence, and optimization.

The complexity of the presented Home UbiHealth model exceeds the efficiency of analytical mathematics to formally describe its components, their functionality, and their interactions. Set Theory and Algebra can hardly offer formal descriptions of the involved interactions and model's behavior. Thus, alternative mathematical methods must be employed to represent and manipulate

all the involved quantities in order to allow the handling of the static and the dynamic properties of the model.

To this end, *Denotational Mathematics* (Wang, 2012) can provide the necessary efficiency and flexibility for the formal representation of the Home UbiHealth model. The formally presented mathematical premises must be capable of approaching self-referenced systems, such as the ones formed in the Home UbiHealth model. Also, they shall include the patient as part within (i.e., observed) and outside (i.e., observer) of the formed system. The model must provide the means to administer formal knowledge representations, manipulate algebraically controlled operations, formally describe behavioral abstractions, and handle dynamically changing content.

Finally, the Home UbiHealth model must tackle security issues at design-time, satisfying the technical and medical requirements. Thus, security is approached as a framework consisted of complete processes, participating and rectifying the system's behavior. The security framework is distinguished into infrastructural and application parts that correspond to the designer's and the user's degrees of freedom, respectively. Infrastructural security includes processes that ensure proper accommodation and facilitation of the carried processes of the Home UbiHealth model. The application security framework consists of the interrelated procedures that act as features to the carried end-user's processes and reflect to the medical constraints. Therefore, security must be considered during both the design and operation of the Home UbiHealth model, in order to ensure the proper management and administration of human lives.

FUTURE RESEARCH DIRECTIONS

The ongoing technological progress offers the opportunity to include home healthcare services among the formal components of healthcare systems. In particular, Home UbiHealth can

become an intermediate layer between primary and secondary healthcare systems (see Figure 2). As a consequence, novel medical professional specializations may appear in order to meet the emerging needs of healthcare services at home. For the realization of a formal home healthcare model, research efforts are required in medicine, nursing, computer science and engineering, oriented towards the Home UbiHealth paradigm. Nevertheless, computer simulation and optimization can accelerate scientific developments in home healthcare and bring it closer to real-world implementations. Thus, they appear to be fertile ground for future research.

Regarding technological aspects, the need for direct and indirect physiological signals, data, and information processing methods, reveals the necessity for efficient parallelization and data fusion applied upon configurable software applications capable of promoting personalization. Additionally, further research is needed on ad-hoc wireless networks, which suffer frequent interrupts due to the lack of continuous power supply, along with the unavailability of standardized communication protocols that meet the Home UbiHealth model requirements. Also, standardization of context-awareness is required in order to optimize the structure of future decision-support systems. Moreover, additional research is needed on the optimization of the underlying communication systems in order to be capable of supporting the increasing number of the dispersed sensors and actuators, as well as the carried mobile and implanted devices. This can reduce the time response of the entire system. Finally, cognitive research approaches must be considered to decrease the computational overheads aiming at the avoidance of analytical calculations to figure out the most adequate responses.

CONCLUSION

The Home UbiHealth model relies on the ubiquitous computing principles and characteristics

Figure 2. Home UbiHealth's place in the pyramid of healthcare

of context-awareness. The model processes contextual raw data that can be transformed into information which, in turn, produces knowledge supported by adequately designed medical ontologies. Knowledge representations and knowledge management provide the means to develop a formal model for treating patients of all categories at home. The model introduces the capability to control medical conditions at home, providing alternatives to the existing healthcare systems and hospitalization models. Thus, the Home UbiHealth model can have financial, social, and environmental impact through the personalization of the provided treatments and the transparent participation of healthcare stakeholders, including the related segments of the market.

The compound design of the Home UbiHealth model along with the complex workflows of its processes exceeds the capabilities of analytical

mathematics. Alternative mathematical approaches are required to ensure the necessary formality in the involved descriptions of the model, providing efficient and effective expressiveness of the occurring healthcare situations. Recent research has offered evidence that Denotational Mathematics provide the capability to efficiently represent and describe the model's static and dynamic behavior. Moreover, Denotational Mathematics provide a conceptual system framework to administer the involved entities with algebraic tools. This increases the efficiency of the model and facilitates the use of established Systems Theory and Control Theory principles and methods. Thus, the Home UbiHealth model simultaneously considers the patient acting as observer of the system or independently performing as controller of its underlying control system.

KEY TERMS AND DEFINITIONS

Calm Computing: Describes the calm (quiet) participation of computing in the interaction with the user without claiming exclusive attention.

Denotational Mathematics: Refers to advanced mathematical entities utilizing objects and conceptual abstractions, defining and manipulating complex relations, representing and administering knowledge, and expressing and handling formally behavioral aspects of executing processes without needing analytical mathematics. The involved mathematical processing is performed on algebraic abstractions denoting mathematical functionalities that obey axioms and laws in order to support the denotational and expressive needs in cognitive informatics, computational intelligence, software engineering, and knowledge engineering.

Internet of Things (IoT): Used to depict the connection of physical objects to the internet with the capability to introduce their identity and communicate with other devices exchanging data. Using the producer-consumer scheme over the internet, the IoT paradigm allows machine produced data to be exploited by other machines.

Knowledge Representation: Required for expressing intelligence and it concerns views of explicit instantiations of conceptual abstractions

to facilitate knowledge sharing and exchange. The conceptual abstractions are formed by processed and interacting entities such as concepts, ideas, processes, and rules.

Pervasive Computing: Refers to the embodiment of computers into physical objects connected into networks, that are consistently available, exchanging information, existing everywhere and operating whenever and wherever needed. The term is used interchangeably with Ubiquitous Computing or UbiComp.

Personalized Healthcare Treatment: Refers to any biologic information that can assist in feasibly predicting on-time the occurrence of a disease or prognosticating a patient's response to a given treatment. It is used synonymously with Personalized Medicine which implies additional scientific aspects relying on the molecular basis of diseases with roots in genetics and genomics.

UbiHealth: Refers to the support of healthcare services taking place in a ubiquitous computing environment.

Ubiquitous Computing (UbiComp): The unobtrusively participation of computing at anytime and anywhere allowing users to interact naturally the way someone is using eyeglasses, without any additional effort.

Multifaceted Applications of the Internet of Things

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

The Internet of Things (IoT) is a new world for connecting every object of the real world with the virtual space in the computer world (Erguler, 2015). The vision of the IoT predicts a future Internet incorporating smart physical objects that offer the hosted functionality as the IoT services (Dar, Taherkordi, Baraki, Eliassen, & Geihs, 2015). IoT refers to the uniquely identified computing devices that are connected to the Internet and embedded into things (Salim & Haque, 2015). The IoT paradigm envisions the pervasive interconnection and cooperation of smart things over the current and future Internet infrastructure (Ziegeldorf, Morchon, & Wehrle, 2014).

The IoT is enabled through several technologies ranging from communication systems to distributed intelligence (Moschakis & Karatza, 2015). The IoT is a new stage of intelligentization and informatization development (Ning & Hu, 2012). The IoT is envisioned as a natural evolution of the Internet, promising to enable the ubiquitous connections for pervasive objects (Ren, 2011). The IoT envisions some services that require both end-device mobility and high availability or high bandwidth (Sonntag & Suomi, 2015). The IoT envisions to connect many sensors to the Internet (Perera, Zaslavsky, Christen, & Georgakopoulos, 2014).

The IoT includes various kinds of devices (e.g., sensors, actuators, radio frequency identification (RFID) tags, smartphones, and backend servers), which are different in terms of size, capability, and functionality (Nguyen, Laurent, & Oualha, 2015). RFID solutions can be utilized

to reduce the operating costs through decreasing labor costs, enhancing automation, improving tracking and tracing, and preventing the loss of materials (Kasemsap, 2015a). Smart objects are generally added to the Internet using IPv6 over Low-power Wireless Personal Area Networks (6LoWPAN), which defines IP communication for resource-constrained networks (Raza, Duquennoy, Höglund, Roedig, & Voigt, 2014).

This article aims to bridge the gap in the literature on the thorough literature consolidation of the IoT. The extensive literature of the IoT provides a contribution to practitioners and researchers by describing the multifaceted applications of the IoT in order to maximize the business impact of the IoT perspectives.

BACKGROUND

The IoT is a paradigm where everyday objects can be equipped with identifying, sensing, networking, and processing the capabilities that will allow them to communicate with one another and with other devices and services over the Internet to accomplish the strategic goals (Whitmore, Agarwal, & Xu, 2015). Mashal et al. (2015) indicated that different types of smart devices are interconnected and communicate via Internet Protocol that creates a worldwide ubiquitous and pervasive network called the IoT.

With the emergence of Internet Protocol-related IoT devices (Shelby & Bormann, 2009) and the concept of embedded Web services (Shelby, 2010), enterprise level applications (e.g., business processes) are extended (Caracas, 2012) to opti-

mize their execution by collecting the real-time information provided by the IoT devices. Business process modeling (BPM) methodologies provide business users with the ability to model their business processes and to implement business models (Kasemsap, 2016a). Logistics efficiency (Guinard, Trifa, Karnouskos, Spiess, & Savio, 2010), safety processes for storing hazardous materials (Mahlknecht & Madani, 2007), and the remote patient monitoring (Yao, Chu, & Li, 2012) are the major IoT applications.

The IoT applications have been adopted in many different domains (Mashal et al., 2015). Several researches focus on the field of health care systems (Pang et al., 2015), rehabilitation systems (Fan, Yin, Xu, Zeng, & Wu, 2014), and systems assisting peoples with disabilities (Domingo, 2012). In order to improve the quality of human life, IoT technology is broadly utilized to create the smart environments, such as smart homes (Gao, Ling, & Yuan, 2011), smart buildings (Tao, Yajuan, Deyun, Junqi, & Hongke, 2010), and smart cities (Theodoridis, Mylonas, & Chatzigiannakis, 2013) which include intelligent transportation and logistics (Chen, Guo, & Hu, 2010), bus systems (Eberle, 2007), and smart parking management (Bechini, Marcelloni, & Segatori, 2014). The IoT paradigm promises to increase the visibility and awareness of energy consumption (Shrouf & Miragliotta, 2015).

CHALLENGES AND IMPLICATIONS OF THE INTERNET OF THINGS

This article highlights the overview of the IoT and the multifaceted applications of the IoT.

Overview of the Internet of Things

The Internet of Things (IoT) has attracted tremendous attention all over the world and is considered as the third wave of information industry (Mashal et al., 2015). In recent year, the IoT has drawn

significant research attention (Li, Xu, & Zhao, 2015). The effective strategy of the IoT can help firms reach the emerging opportunities from the IoT and improve their competitive advantage (Li, Hou, Liu, & Liu, 2012). The IoT refers to the information exchange and communication between anything and the Internet to realize the intelligent recognition, positioning, tracking, monitoring, and management (Wang, Xie, Wang, & Jia, 2011). The IoT, which is established over architectures of wireless sensor networks (WSNs), provides an actual platform for various applications of personal and ubiquitous computing (Guo, Zhang, Sun, & Bie, 2014).

Structure of a classical IoT is divided into three layers (Jia, Feng, Fan, & Lei, 2012). The first layer is the perception layer that recognizes objects and gather their information (Erguler, 2015). The second layer is the network layer which is responsible for the transmission of the collected data from the perception layer to the corresponding application systems through Internet and mobile telecommunication network. The last layer is called the application layer, where applications are executed to process information and serve to users. As IoT generates massive amount of useful data, data mining techniques play an important role in making IoT applications smart enough to provide the adequate services and enable improved environments (Mashal et al., 2015).

There have been several conducted studies and surveys that are relevant to the security in the IoT (Miorandi, Sicari, & Pellegrini, 2012). For instance, Wang et al. (2006) gave the detailed survey of security issues in WSNs, which can be considered as a reference for the IoT. Atzori et al. (2010) focused on authentication, data integrity, and privacy issues in the IoT, particularly in RFID systems and sensor networks. Kumar and Patel (2014) provided the general overview of security and privacy issues in the IoT. Kumar and Patel (2014) explained the description of different security threats and privacy concerns while processing, storing, and transmitting the data.

Multifaceted Applications of the Internet of Things

The IoT represents the future technology trend of sensing, computing, and communication (Guo et al., 2013). The IoT and its relevant technologies have been attracting the attention of researchers from academia, industry, and government in recent years (Tsai, Lai, & Vasilakos, 2014). The IoT is recognized as one of the most important areas of future technology and is gaining vast attention from a wide range of industries (Lee & Lee, 2015). The IoT extends the capabilities to identify products with the new technologies, such as near field communication, RFID, quick response code and with the existing identification technologies, such as barcodes (Jara, Parra, & Skarmeta, 2014).

Lee and Lee (2015) indicated that five IoT technologies used for the deployment of successful IoT-based products and services include RFID, WSNs, middleware, cloud computing, and the IoT application software. RFID technology constitutes an important part of what has become known as the IoT toward establishing the dynamic and complex environment (Rekleitis, Rizomiliotis, & Gritzalis, 2014). RFID allows automatic identification and data capture using radio waves, a tag, and a reader (Lee & Lee, 2015). The tag can store more data than traditional barcodes. The tag contains data in the form of the Electronic Product Code (EPC), a global RFID-based item identification system developed by the Auto-ID Center. Adaptation of RFID and wireless sensor networking technologies can make the revolution of the IoT (Gubbi, Buyya, Marusic, & Palaniswami, 2013). For RFID-based IoT, objects are identified by the RFID readers that are connected to the servers through Internet for processing data intelligently. Mobile handsets (e.g., netbooks, cellular phones, and tablet computers) act as RFID readers that efficiently scan and gather the information about RFID-tagged items (Erguler, 2015).

WSNs include the spatially distributed autonomous sensor-equipped devices to monitor the physical or environmental conditions and can

cooperate with the RFID systems to better track the status of things, such as their location, temperature, and movements (Atzori et al., 2010). WSNs consist of a large number of small, inexpensive, and resource-limited devices called sensors, which are used to collect the physical world data that is wirelessly transferred to a central location known as a Sink or Base Station (Mashal et al., 2015). These sensor devices communicate with each other using different proprietary protocols, such as ZigBee (Usman & Shami, 2013). WSNs have primarily been utilized in the cold chain logistics that employ the thermal and refrigerated packaging methods to transport the temperature-sensitive products (Hsueh & Chang, 2010).

Middleware is a software layer interposed between software applications to make it easier for software developers to perform the communication and input/output (Lee & Lee, 2015). Its feature of hiding the details of different technologies is fundamental to free IoT developers from software services that are not directly relevant to the specific IoT application. Many IoT applications require massive data storage, huge processing speed to enable the real-time decision making, and high-speed broadband networks to stream data, audio, and video. Regarding IoT application software, the IoT facilitates the development of industry-oriented and user-specific IoT applications (Lee & Lee, 2015).

Whereas devices and networks provide the physical connectivity, IoT applications enable device-to-device and human-to-device interactions in a reliable manner. The IoT applications on devices need to ensure that messages have been received in a timely manner. For example, transportation and logistics applications monitor the status of transported goods, such as fruits, fresh-cut produce, meat, and dairy products. FedEx uses SenseAware to keep tabs on the temperature, location, and other vital signs of a package. While device-to-device applications do not necessarily require data visualization, more and more human-centered IoT applications provide visualization to present information to end users in an intuitive way

and to allow the interaction with the environment (Lee & Lee, 2015).

The recent emerge of the IoT changes the teaching and learning process in global education (Uzelac, Gligoric, & Krco, 2015). Smart classrooms can be defined as intelligent environments equipped with an assembly of many different kinds of hardware and software modules, such as projectors, cameras, sensors, and face recognition module (Xie, Shi, Xu, & Xie, 2001). Another smart classroom environment that is based on the IoT technology presents a system that can detect the level of students' interest in near real-time with 80 percent accuracy (Gligoric, Uzelac, Krco, Kovacevic, & Nikodijevic, 2015).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of the IoT will provide the potential opportunities for future research. Human-computer interaction (HCI) is the study of how people design, implement, and utilize the interactive computer systems, and how computers affect individuals, organizations, and society through human-computer interfaces. Cloud computing includes network access to storage, processing power, development platforms, and software (Kasemsap, 2015b). Cloud computing is a model for on-demand access to a shared pool of configurable resources (e.g., compute, networks, servers, storage, applications, services, and software) that can be easily provisioned as Infrastructure as a Service (IaaS), Platform as a Service (Paas), and Software and applications (SaaS). SaaS represent the largest cloud market and are still growing quickly. SaaS utilizes the Web to deliver applications that are managed by a third-party vendor and whose interface is accessed on the clients' side. HCI, cloud computing, SaaS, and the IoT are certain to remain important topics for future research.

The adoption of Big Data becomes the foundation of competition and growth for individual

firms, enhancing productivity and creating significant value for modern business by reducing waste and increasing the quality of products and services. Web 2.0 describes a set of next-generation Internet technologies. These protocols and tools make it easier to create online applications that behave dynamically, much like traditional PC-based software. The Semantic Web (also known as Web 3.0) represents the next major evolution in connecting information, thus enabling data to be linked from a source to any other source recognized by computers. Leaders of virtual support teams may need to assume a coordinating role to ensure effective collaboration and communication among virtual team members through information technology (Kasemsap, 2016b). The relationships among the IoT, Big Data, Web 2.0, the Semantic Web, and virtual team will be the influential issues for future research directions.

CONCLUSION

The overview of the IoT and the multifaceted applications of the IoT are emphasized in this article. The IoT is made up of hardware and software technologies regarding WSNs, robotics, RFID, and cloud computing. The IoT describes the modern world in which everyday objects are connected to a network so that data can be effectively shared. The IoT refers to the networking of physical objects through the application of embedded sensors, actuators, and other devices that can collect and transmit information about the objects. Optimum utilization of energy and resources can be achieved by adopting the IoT-related technology. IoT proves to be very helpful to people in their daily routines by making the appliances communicate to each other in an effective manner, thus saving energy and cost.

The IoT enables the multifaceted applications ranging from the micro to the macro, and from the trivial to the critical perspectives. Due to physical objects getting connected and controlled digitally

and centrally with wireless infrastructure regarding the IoT, there is a large amount of automation and control in global operations. Without human intervention, the IoT-related machines are able to communicate with each other leading to faster and timely output. The IoT allows individuals to automate and control the tasks that are accomplished on a daily basis, avoiding human intervention. All the applications of the IoT accomplish in increased comfort, convenience, and better management, thus improving the quality of life.

However, there are many disadvantages of utilizing the IoT. The IoT presents a variety of potential security risks that could be exploited to harm consumers by enabling unauthorized access and misuse of personal information. Prominent technical limitations that may affect the growth and use of the IoT include a lack of new Internet addresses under the most widely used protocol, the availability of high-speed access, wireless communications, and lack of consensus on technical standards. A potential barrier to the development of IoT is the technical limitations of the version of the Internet Protocol that is widely utilized. To solve the IoT-related problems, organizational executives and government officials must work together to create practical standards, develop new technologies, and provide best practices for the Internet and Internet-enabled devices, toward promoting the utilization of the IoT.

KEY TERMS AND DEFINITIONS

Computer: The electronic machine that is used for storing, organizing, and finding words, numbers, and pictures, for doing calculations, and for controlling other machines.

Internet: The worldwide computer network that provides information on many subjects and enables users to exchange messages.

Network: A number of computers that are connected together so that they can share information.

Radio Frequency Identification: The automatic identification of packages, products, machinery, etc., through attached transponders.

Sensor: The device that is utilized to record that something is present or that there are changes in something.

Technology: The use of scientific knowledge to solve practical problems, especially in industry and commerce.

The Internet of Things: All the different devices, including computers, phones, wearable technology, and smart systems, that are able to connect to each other utilizing the Internet.

The Role of U-FADE in Selecting Persuasive System Features

Isaac Wiafe

Ghana Institute of Management and Public Administration, Ghana

INTRODUCTION

Behavior Change Support Systems (BCSS) are systems that combine properties of interpersonal interaction and mass communication with the support of technology to change or alter human behavior or attitude (Oinas-kukkonen, 2013). It originated from Persuasive Technologies (PT) or Captology; which is the use of interactive technology for changing human attitude or behavior to a predetermined one (Fogg 1997). Due to its ability to adapt to individual differences, it is considered to have a greater potential for changing human behavior and/or attitude. This is because, it is capable of employing both animated and non-animated objects to persuaded its user. Thus it has been applied in areas of healthcare (Mateevitsi et al., 2014; Rana & Saleem, 2014), leisure and recreation (Sra & Schmandt, 2013; Tieben, Sturm, Bekker, & Schouten, 2013), energy saving (Emeakaroha, Ang, & Yan, 2012; Wunsch, Stibe, Millonig, & Seer, 2015) Information security (Kegel & Wieringa, 2015; Yeo, Rahim, & Ren, 2009), etc. Nonetheless, BCSS development is faced with a number of challenges and one of the most prominent is that majority of designers fail to use appropriate methods for its design (Wiafe, 2013). As a result, some BCSS applications become obsolete with time[2]. In addition, most of the existing frameworks or design approaches do not provide adequate information that can be used for analyzing and designing applications that address changing needs of users during use

Recently, the Unified Framework for Analyzing, Designing and Evaluating persuasive systems (U-FADE) was proposed (Wiafe 2013). It incorporated key concepts from existing persuasive design models such as the Functional Triad (B. Fogg, 1998)(Wiafe et al., 2014), the Behavior Wizard (B. J. Fogg & Hreha, 2010)[4], the 3-Dimensional Relationship between Attitude and Behavior (3D-RAB) model (Wiafe, Nakata, & Gulliver, 2014) [1], [2] and the Persuasive System Design (PSD) model (Oinas-kukkonen & Harjumaa, 2009) ADDIN CSL_CITATION { "citationItems": [{ "id": "ITEM-1", "itemData": { "author": [{ "dropping-particle": "", "family": "Fogg", "given": "B J", "non-dropping-particle": "", "parse-names": false, "suffix": "" }, { "dropping-particle": "", "family": "Hreha", "given": "Jason", "non-dropping-particle": "", "parse-names": false, "suffix": "" }], "id": "ITEM-1", "issued": { "date-parts": [["0"]] }, "title": "Behavior Wizard: A Method for Matching Target Behaviors with Solutions 1. Overview of Behavior Wizard 3. However, the framework has not been applied in developing any application to ascertain its practicality, although it has been demonstrated conceptually that it provides a more compressive approach for BCSS analysis and design (Wiafe 2013)(B. J. Fogg & Hreha, n.d.).

This chapter therefore presents an evaluation of the Unified Framework for Analyzing and Designing Persuasive Systems using the case of a weight management system. The various

stages of the U-FADE was followed to redesign an existing mobile application known as ObiMo Pet (Wiafe, 2013). The objective was to ascertain whether the framework is capable of facilitating design or enhancing the selection of persuasive system features.

The chapter is presented as follows: the next section presents a background discussion on U-FADE, this is followed by the method adopted for the study, and then the process in U-FADE is used to redesign the existing application. The findings, discussions, future research directions and conclusions are then presented.

BACKGROUND

Currently, the Unified Framework for Analyzing, Designing and Evaluating persuasive systems (U-FADE) is the only framework that seeks to formalize Behavior Change Support Systems (BCSS) design process with emphasis on the changing needs of users during the change intervention (B. Fogg, 2002)(Wiafe 2013). It comprises analysis of the Persuasion Event, selection of Persuasion Strategy, identification of System Features needed to promote persuasion, Development and Implementation of the persuasive system and the Evaluation of Change (See Figure 1)1. ADDIN CSL_CITATION { "citationItems": [{ "id": "ITEM-1", "itemData": { "DOI": "10.4018/ijcssa.2013070102", "ISSN": "2166-7292", "author": [{ "dropping-particle": "", "family": "Wiafe", "given": "Isaac", "non-dropping-particle": "", "parse-names": false, "suffix": "" }], "container-title": "International Journal of Conceptual Structures and Smart Applications", "id": "ITEM-1", "issue": "2", "issued": { "date-parts": [["2013", "6"]] }, "page": "6-16", "title": "U-FADE: A Unified Approach To Persuasive Systems Development", "type": "article-journal", "volume": "1" }, "uris": ["http://www.mendeley.com/documents/?uuid=8279677e-cf51-47d4-a16a-6fccdb5e387e"] }], "mendeley": { "formattedCitation": "(Wiafe, 2013)", "plain-

TextFormattedCitation": "(Wiafe, 2013)", "previouslyFormattedCitation": "[4]", "properties": { "noteIndex": 0 }, "schema": "https://github.com/citation-style-language/schema/raw/master/csl-citation.json" } The main benefit of using U-FADE is its ability to provide a thinking guide for both novice and expert persuasive system developers. It explores the problem space by identifying variations in users' cognitive dissonance state and the situational (or environmental) context to guide designers to select persuasive features for specific targets. This is made possible by employing activities in the Event Analysis which are the Use and User context analysis: concepts that were borrowed from the PSD model (Oinas-Kukkonen and Harjuma 2009). In User context analysis, the framework emphasized the need for the identification of internal and external factors that affect individuals to change or maintain behavior.

Here, the 3D-RAB model serves as a tool for the designer to group potential users into various categories based on inconsistencies in their attitude and behavior. The next step in Event analysis is Use context analysis. This considers BCSS application design in relation to formal and informal behavior change factors [2]. It is argued that, designers need to consider both formal and informal activities within their immediate environment that may interact or influence potential users to change their behavior. The persuasive technology onion provides steps that enable designers to categorize attitude and behavior change as planned or natural based on existing environmental factors. Natural Attitude or Behavior Change (NABC) takes into account activities within an environment that changes an individual's behavior or attitude naturally. Issues relating to culture, social norms, beliefs, ethics, commitments and values among others are of paramount interest. Arguably, these issues are exceptionally essential for BCSS designs since their key aim is to alter behavior or attitude. ADDIN CSL_CITATION { "citationItems": [{ "id": "ITEM-1", "itemData": { "DOI": "10.4018/ijcssa.2013070102", "ISSN":

"2166-7292", "author": [{ "dropping-particle": "", "family": "Wiafe", "given": "Isaac", "non-dropping-particle": "", "parse-names": false, "suffix": "" }], "container-title": "International Journal of Conceptual Structures and Smart Applications", "id": "ITEM-1", "issue": "2", "issued": { "date-parts": [["2013", "6"]] }, "page": "6-16", "title": "U-FADE: A Unified Approach To Persuasive Systems Development", "type": "article-journal", "volume": "1" }, "uris": ["http://www.mendeley.com/documents/?uuid=8279677e-cf51-47d4-a16a-6fccdb5e387e"] }], "mendeley": { "formattedCitation": "[5]", "plainTextFormattedCitation": "[5]", "previouslyFormattedCitation": "(Wiafe, 2013)", "properties": { "noteIndex": 0 }, "schema": "https://github.com/citation-style-language/schema/raw/master/csl-citation.json" }. Next, Planned Attitude or Behavior Change (PABC) is considered. PABC consists of existing approaches that are used on persuadees to change their behavior or attitude intentionally. This may include automated and non-automated approaches.

The Event Analysis provides designers the ability to identify existing activities that needs to be promoted to ensure that target behavior is achieved. Particularly, the U-FADE approach claims that designers must reinforce the existing overt or covert persuasive activities that are identified during Event analysis. Additionally, it proposes steps that guide designers to identify system features by focusing on incremental changes as suggested by Fogg (2009) and Oinas-Kukkonen (2009). Transitions that involve attitude-changing states must use logical arguments (elaborated messages) to ensure a long-term change, whereas heuristics (peripheral messages) must be used for short-term behavior change.

Designers are also encouraged to identify a list of familiar hardware and select those that the application can be deployed on [5]. In this process, they must pay attention to cost, environment and obtrusiveness of the technology they chose. Specifically, the introduction of a new hardware should be considered or used only when the ap-

plication cannot be administered effectively on an existing device or technology that is familiar to the potential persuadees.

The framework also provides a guide on how 28 system features (Oinas-kukkonen & Harjumaa, 2009; Torning, Hall, & Oinas-kukkonen, 2009) may support either elaboration or peripheral message routes (Wiafe et al., 2014). The approach is based on findings from the Use and User analysis. It is also emphasized that to enable designers to focus on design-relevant issues, a Transition Description Card should be used. The card provides a template for summarizing all the activities performed during the analysis.

The last step in U-FADE is the provision of methods for evaluating changes in persuadees to enable designers to modify system features during use.

From the above discussions it can be concluded that U-FADE's approach for developing BCSS applications seeks to gather and analyze user requirements by identifying: the distribution of cognitive dissonance levels of potential user, existing activities that supports or prevent potential users from performing the target behavior and select persuasive system features and device based on these identified activities.

As already mentioned, and to the best of our knowledge, the framework has not been applied for the design or development of any application, thus one cannot substantiate its appropriateness and effectiveness with any empirical evidence. Although it can be argued that the author conceptually demonstrated and evaluated its effectiveness, relevance and design implications, it is essential for it to be demonstrated practically.

The next section is a discussion on methods that were adopted to evaluate the benefits of using U-FADE for designing BCSS.

RESEARCH APPROACH

A designed artifact must map adequately to the real world, solve a problem and its relevance must

be demonstrated to justify the need for a design research (Hevner, March, Park, Ram, & Ram, 2004). Hence to practically demonstrate whether the framework is useful, it was used to develop a BCSS application. This is to say that U-FADE was applied to the development of an existing BCSS application that seeks to encourage its users to reduce calorie intake and manage their weight. The application considered in this case is known as ObiMo Pet (Wiafe & Nakata, 2012) and the system features that were realized after the analysis were compared to the existing one.

Potential Persuadees

Employees of Accra Polytechnic were considered for the study as potential users (potential persuadees). The Polytechnic is a tertiary institution located in Accra, the capital of Ghana. It was established in 1949 as the first polytechnic in the country. Currently, it offers Higher National Diploma (HND) programs in Science and Engineering, Fashion Design, Social Science, Hotel Catering and Institutional Management, etc. with a total staff population of over 600.

The Institute has keen interest in issues relating to staff healthcare thus it has recently built a state of the art gymnasium for staff. Additionally, healthier lifestyle seminars series are organized regularly to refresh staff on the need for maintaining good health by the Hotel Catering and Institutional Management department. It has a strong staff welfare association that also seeks to promote social welfare activities within the Institute. Amidst all these efforts, the ratios of overweight and obese persons continue to increase.

The ObiMo Pet

ObiMo Pet (Torning et al., 2009) is a weight management system designed to manage calorie intake and physical activities of its users. It uses persuasive strategies to motivate users to maintain healthier lifestyles as they cater for a virtual pet of their choice. It provides them with physical activities

and diet plans that seek to manage their weight. As persuadees adhere to suggestions provided by the application, they earn points to decorate their virtual pets. Also, ObiMo recognizes persuadees whose pet is the most decorated in the virtual community. This encourages them to compete with their peers as they seek to accomplish their target goals (i.e. manage their weight).

Six system features were used in the application to promote behavior change. These are reward, suggestion, tailoring, recommendation, competition and personalization. In addition, the semiotic approach to information systems development (Liu, 2004, p. 37) was adopted as the foundation for analysis and design.

Design Objectives

The study targeted a weight loss between 3 and 5 pounds a week, and consumption of 2300 calories a day. It is however acknowledge that the actual amount of calorie intake and calorie burnt is oversimplified in this study; since the values normally varies according to the individual's gender, type of work or activity level, age, body weight, etc.

Additionally, although U-FADE suggests the reassessment of user behavior to evaluate incremental behavior change, this was not considered as part of the objectives of this study. The next section reports findings from the analysis.

ANALYSIS AND DESIGN

Event Analysis

As apart of User Context analysis (the first step in Event Analysis), a questionnaire was developed to collect data and classify users into various cognitive dissonance states

```
ADDIN CSL_CITATION {

  "suffix": "" } ], "container-title": "International Journal of Conceptual Structures and Smart Applications", "id": "ITEM-1", "issue": "2", "issued": { "date-parts": [ [ "2013", "6" ] ] }, "page": "6-16", "title": "U-FADE: A Unified Approach To Persuasive Systems Development", "type": "article-journal", "volume": "1", "uris": [ "http://www.mendeley.com/documents/?uuid=8279677e-cf51-47d4-a16a-6fccdb5e387e" ] } ], "mendeley": { "formattedCitation": "(Wiafe, 2013)", "plainTextFormattedCitation": "(Wiafe, 2013)", "previouslyFormattedCitation": "[4]", "properties": { "noteIndex": 0 }, "schema": "https://github.com/citation-style-language/schema/raw/master/csl-citation.json" }. The classification was based on variations in cognitive dissonance (Festinger, 1957) of users' attitude and behavior (i.e. Attitude Towards Target Behavior, Attitude Towards Change or Maintaining Behavior, and Current Behavior (CB)) in relation to food menu goals (calorie intake) and workout goals (calories burnt). Target behavior was considered as maintaining a Body Mass Index (BMI) value between 18.5 and 25.
```

A pilot study was conducted to test the clarity and consistency of the questionnaire and the suggested amendments were made. Finally, the questionnaire was distributed to staff members of the Institution. One hundred and seventeen responses were received after one month of distribution. Three questions each were asked to measure respondents' Attitude Towards Target Behavior (ATTB) and Attitude Towards Change or Maintaining Behavior (ATCMB) in order to ensure reliable and consistent responses. Cronbach's alpha with reliability coefficient of 0.7 was used to check for reliability. Respondents were classified into positives or negative ATTB, ATCMB or CB by computing the averages of the numerical values they assigned to each question. The distribution of cognitive dissonance states for the 117 responses is presented in Table 1.

From Table 1, thirty-nine respondents (representing 33%) were identified to be in state 1 where all three values (ATTB, ATCMB and CB)

Table 1. Distribution of cognitive dissonance state observed

State	CB	ATTB	ATCMB	Response	Percent (%)
1	+	+	+	39	33
2	+	+	-	12	10
3	+	-	+	0	0
4	+	-	-	6	5
5	-	+	+	42	35
6	-	+	-	6	5
7	-	-	+	0	0
8	-	-	-	12	10
Total				117	100

are positive and users are considered to be in the “ideal” state. With all things being equal they are expected to continue to maintain a BMI that is between 18.5 and 25. However majority of the respondents were found to be in states that need a change in either attitude (ATTB/ATCMB) or behavior (CB). None of the respondents was in state 7, i.e. no staff was identified to have a BMI that is not between 18.5 and 25, and also do not believe that they should maintain a BMI value between 18.5 and 25 but would want to change. Likewise, no respondent was in state 3, where CB is positive, ATCMB is positive, but ATTB is negative. Forty-two respondents (representing 35%) were identified to be in state 5. These are individuals who do not have BMI between 18.5 and 25, but believe that there is a need for them to change their current BMI values. According to Wiafe, Nakata, and Gulliver (2014) these users experience a strong form of cognitive dissonance which serves as a motivating factor for changing their behavior. Table 1 indicates that, potential users of the system are experiencing different forms of cognitive dissonance levels. This therefore suggests that it will require different persuasive system features or properties to persuade them. Although in U-FADE it is argued that persuasive systems or technologies should ensure that they provide specific persuasive features for all states, for the purpose of this study only users in state 5 were considered.

The next stage of the analysis collected information regarding the Use context (i.e. PABC and NABC). Informal interactions, interviews and discussions were used to gather relevant information pertaining to this. Seven observations were identified to impact staff attitude and behavior in relation to maintaining a healthier BMI. Some of these are societal norms and culture, availability and access to technology, the existence of staff association, etc. The observations and associated suggested persuasive features identified to be appropriate for users in state 5 are summarized in Table 2.

Persuasive Strategy

The selection of technology must aim at identifying the most convenient hardware that is readily available, affordable and also familiar to potential users of the system[5]. Hence a mobile device was considered to be appropriate since each staff member owns a mobile device. This was realized during the Use analysis. Also since users with positive ATTB and ATCMB who perform negative behavior (not maintaining a between 18.5 and 25) are more likely to change if peripheral messages are used (Wiafe, 2013), the peripheral route was considered to be the most appropriate channel for the design.

Table 2. Selected system features identified to promote weight management for the target population

Observation	Description	System Feature (Peripheral route)	Implementation
Societal norms	Ghanaians perceive overweight people as wealthier and rich: this serves as a negative impact on the target behavior	Social facilitation	The system should provide a platform for discussion to counter the notion associated with being overweight
Hotel Catering and Institutional Management department	There is a Nutrition and Home Science unit at the institute with scholars in nutrition	Social role	An avatar of one of the renowned scholars in the unit should be used to suggest healthier menus
Intellectual and competitive environment	This is an educational institution made up of intellectuals who prefer to demonstrate that they can march their peers	Social comparison Competition	The system should provide a means for peers to compete
Staff association	There is an association for staff of Accra polytechnic employees: they meet regularly to discuss their welfare	Normative influence	The system should provide a means to make users know that the target behavior is a collective goal
Expensive and Poor Healthcare facilities	Healthcare cost is becoming expensive and in addition there are few healthcare facilities in the country	Reminders	The system should provide a means of reminding users of the increasing cost of healthcare and poor medical facilities
Rising cost of food prices	The cost of food prices continuous to increase due to high inflation	Suggestion	Suggest alternative cheaper and healthier menus
Gymnasium	The availability of a state of the art gym serves as a positive impact to the target behavior Some staff also believe that they are taxed indirectly to maintain the gym	Reminder	Prompt staff to use the gym regularly since they believe they are paying for its maintenance
		Suggestion	An avatar of the gym instructor should be used to suggest exercise schedules

Selection of System Features

Although a number of system features were identified during the analysis, only those that support heuristics (peripheral messages) were considered. This is because the study limited its design principles to users in state 5 (those with positive attitude), hence there is no need to change their attitude. Rather, emphasis is given to peripheral messages that promote behavior change. Social facilitation, Social role, Social comparison, Competition, Normative influence, Suggestions and Reminders were identified to be appropriate for promoting behavior change in this situation. Social role was identified based on the fact that there is a Nutrition and Home Science unit (see Table 2) within the Hotel Catering and Institutional Management department at the Institute. This unit has scholars in nutrition. Since the staff members

are familiar with their colleagues who are experts in areas of nutrition and wellbeing, they are more likely to accept persuasive messages from an avatar (a virtual nutrition scholar) of one of their colleagues who is an expert in the field.

Likewise, the existence of a staff welfare association (see table 2) at the Institute promotes normative influence; consequently, normative influence was also considered as an appropriate system feature.

Refer to Table 2 for the list of system features identified and its associated justification for the selection of these features.

As required by the framework, a Transition Description Card (TDC) was completed for transition 5 → 1 (i.e. changing users with the right attitude but a negative behavior). The assumptions, the type of change, the type of message, constraints, etc. are highlighted on the TDC for the specific

transition. Figure 2 is the TDC for transition 5 → 1 that was realized during analysis.

FINDINGS AND DISCUSSIONS

The analysis facilitated the selection of a specific target group that is “better defined” as compared to the original application. In ObiMo Pet the system was not designed for any particular target group. Indeed, it was assumed that the issue of weight management is generic and thus the designers did not deem it necessary to identify target specific issues. The use of the framework facilitated the identification of a particular group of users (those in state 5). Consequently, it focused its persuasive activities and system features on this type of users. Although one can argue that the other groups of users also need attention, this characteristic of the U-FADE enables the designer to plan or target a specific potential user needs.

Again, even though the analysis focused on users in state 5, it identified seven system features. However five of them were not the same as the ones used in ObiMo Pet. The seven features observed are social role, normative influence, competition, suggestion, social facilitation, social comparison and reminders as compared to tailoring, competition, rewards, suggestions, recommendation and reminders. Out of these, suggestion, competition and reminders were common to both, whereas social facilitation, social comparison, social role and normative influence were not present in ObiMo Pet.

One may therefore argue that ObiMo Pet’s failure to identify these features may be due to the fact that it did not adopt an appropriate approach to analyze the design of the BCSS application. Rather, the designers used a generic analysis and design methodology (the semiotic approach to information systems development). More importantly, the approach used for analyzing and designing of ObiMo Pet failed to identify these features although the application targeted a larger population as compared to the target users

for this analysis (potential users in state 5). This therefore suggests that using generic Information Systems design methods should not be encouraged in BCSS development.

Also, all the suggested system features seek to promote an existing condition that favors the target behavior or refute an existing belief or perception that impedes the performance of the target behavior. This was not the same in ObiMo Pet. This is to say that, the selection and use of system features was aimed at targeting only behavior change (see table 2). Thus they were all peripheral routes of persuasion.

ObiMo Pet did not provide any substantive justification for the selection and use of the persuasive features. It appears that the designers used an arbitrary approach in the selection process: a practice that is common in existing BCSS applications.

From the study it was observed that one crucial issue appears to be largely ignored in BCSS designs. This relates to how system features are implemented. It was observed that although some system features used in ObiMo Pet were also identified during the analysis, they were implemented differently. For example, In ObiMo Pet, reminders were used to remind users of their daily activities whereas in the analysis it was observed that reminders should be used to make staff use the gym regularly since they pay for the service indirectly. Hence in ObiMo Pet, reminders are used for elaborated messages (targeting attitude change) whereas they are used for peripheral messages (targeting behavior change) in the proposed system. Similarly, suggestion and competition are implemented differently.

With respect to hardware selection, the analysis advocated for the use of a mobile devices, however in ObiMo Pet both mobile and PC were used to implement the application. Again, there was no justification for the need of a PC interface for a weight management system. As observed from the analysis, majority of the users would be comfortable using an app on a mobile device. It is however important to state that ObiMo Pet did consider a

larger audience as compared to what was used for the study. Hence, there is the possibility that the use of a PC may be relevant for other targeted groups that were not considered in this study.

FUTURE RESEARCH DIRECTIONS

Our findings indicated that the framework fails to provide the exact messages that should be used for persuasion, rather it provides specification for the message: suggesting instance in which peripheral messages would be appropriate and those that will require elaboration. Nonetheless, the study cannot conclude that the introduction of additional system features to ObiMo Pet will make it more effective, since there is no empirical evidence to support such a claim. It is therefore recommended that, future research should investigate the relationship between the number of persuasive features and the persuadability of an application. This is to say that the proposed system must be implemented and evaluated in terms of its effectiveness in changing user behavior.

In addition, there is need for further studies to investigate into how system features should be implemented effectively. As observed above although some system features were common to both ObiMo Pet and the proposed application, they aim to present different persuasive messages. This raises a number of research questions relating to the appropriateness of how a system feature is implemented. Specifically will the manner in which a system feature is presented have an effective of the persuadability of a system?

Lastly, although there are a number of studies that have demonstrated that cultural and gender issues play a key role in the selection and design of persuasive system features (Orji, Vassileva, & Mandryk, 2014), the framework failed to establish how gender impacted the selection of persuasive features. Hence there is the need for further studies to identify how the framework caters for gender differences.

CONCLUSION

This chapter has demonstrated the practicality of the Unified Framework for Analyzing and Designing persuasive systems. The design principles of the framework were tested on the objectives of a persuasive weight management system (ObiMo Pet).

Our findings supported the claim that there are variations in cognitive dissonance of users. Users were found in six (6) out of the eight (8) listed states proposed by Wiafe, Nakata, and Gulliver (2014). It was also observed that by applying the U-FADE, newer system features emerge although there was no evidence that these system features will improve the persuadability of a system.

KEY TERMS AND DEFINITIONS

Captology: The study of computers as a persuasive technology.

Elaborate Message: A persuasive messages that are based on logics and they are relevant to the subject of discussion, that seek to alter a change in a receivers attitude.

Peripheral Message: Persuasive messages that uses cues and lacks relevant logic but however seeks to alter human behavior.

Persuadability: The ability of a persuasive technology, system or a behavior change support system to persuade a user to change his or her attitude and/or behavior.

Persuadee: Users of a persuasive technology of a behavior change support system that the designer intends to change.

Persuasive System Features: The features and functionality of a system that solely designed and implement to alter human cognition to a predetermined one.

Transition Description Cards: A template that is used to summarize the findings from a persuasive system design analysis. It aims at providing the designer with content relevant information for developing a persuasive system.

Social Computing

Nolan Hemmatazad

University of Nebraska at Omaha, USA

BACKGROUND

Throughout the last few decades, computational technologies have grown increasingly more capable, useful, and connected at an exponential rate. However, while this general boon in computational power has occurred fairly recently, discussions relating to the ideas of interconnected computational systems and instantaneous, widespread information exchange began much earlier. As one example, we can look to the early efforts of Vannevar Bush, who helped facilitate cooperations between the United States government, business communities, and academicians for the advancement of military-centered scientific research initiatives. This formal cooperation would pave the way for later endeavors, such as the establishment of the Advanced Research Projects Agency (ARPA, and subsequently DARPA) and ARPANET, a precursor to the modern Internet.

The real fruits of early theoretical and engineering groundwork such as this, however, would become apparent on a much larger scale beginning in the 1980's and throughout the early 1990's, a timeframe that marks the development of several early communications technologies, including Usenet (a decentralized system of distributed discussions), Internet Relay Chat (IRC; a real-time, multiparty text communication system), and the World Wide Web (WWW), which would set a new standard for the electronic presentation and dissemination of text and media contents.

Though some of the fundamental characteristics of social computing had already been cemented even within these early technologies — real-time user content distribution, for example, was a

natural prerequisite of Internet-mediated chat — the Web and consumer technologies were still in their infancy. Technical limitations (such as a lack of bandwidth for widespread distribution of rich media, as well as limited processing power available to consumption devices), lack of user adoption, and delayed development of standards for how best to utilize new mediums for communication each constricted the advancement of more powerful social computing applications.

By the start of the new millennium, however, a movement known as “Web 2.0” was quickly gaining traction. The motivation behind this development was to acknowledge the evolving state of 1) consumer Web-enabled technologies, which boasted continuously increasing processing and display capabilities, 2) enhancements to the underlying network infrastructure which allowed for decreased latency and increased throughput of data transmissions across the internet, 3) more widespread adoption of Web technologies, and 4) increased user and developer activity surrounding collaborative and social technologies. As Fischer (2009) observed, this paradigm could be succinctly characterized by its objective of “fostering and supporting social production and mass engagement and collaboration”.

While the term (Web 2.0) itself may have been merely a label — considered little more than jargon even by Sir Tim Berners-Lee, the creator of the Web (Laningham, 2006) — the notions it represented provided the foundation for social computing as we know it today. Through the course of just over a decade, the Web had gone from the nascent realization of a technical dream, to a medium where users could stay constantly

connected via the exchange of text, images, audio, and video media, from the comfort of their home, or abroad with their mobile devices.

Today, social computing-related activities are among the most common uses of networked devices, and the evolution of mobile technologies has established social computing as an outstanding example of pervasive or ubiquitous computing technologies. In fact, recently the terms “pervasive social computing” (see, for example: Mokhtar and Capra, 2009) and “ubiquitous social computing” (for example: Motahari et al., 2007) have been coined to express exactly this dynamic, and to reflect the increasing prevalence of this relationship. Now more than ever, individuals are staying connected with one another via the use of social technologies, and new innovations are quickly being developed to help augment this pervasiveness and the facilitation of social interactions in new and imaginative ways.

With this understanding at hand, the definition of social computing employed within this chapter will be as follows: *The use of computational devices to facilitate or augment the social interactions and content sharing activities of their users, or to evaluate such interactions so as to obtain new information.* This aligns well with previous descriptions from the academic literature (see: Schuler, 1994; Charron et al., 2006; Parameswaran & Whinston, 2007a). Of note, however, is that this definition explicitly acknowledges the use of social computing as an analysis and prediction tool, does not impose limits upon the influence of institutions or providers over the social interactions of their users, and does not exclude anonymous or pseudonymous user interactions from its coverage. The definition is intentionally broad, so as to encompass social computing not only for what it is today, but for what it may become in the not-too-distant future.

PRACTICAL APPLICATIONS OF SOCIAL COMPUTING

The applications of social computing technologies are many and diverse in nature. While this is so,

perhaps the most prominent and widely used of these applications can be seen in general purpose, online social networks. These networks have been defined as “web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system” (Boyd and Ellison, 2007). Typically, such networks allow the exchange of short posts of information or other media contents to a timeline of activity visible to the public, their friends, or a more limited audience. Facebook, Twitter, and Google+ are each well-known examples of online social networks.

Web logs or *blogs* represent another application of social computing principles. Blogs allow users to create content that is typically of greater length than the concise updates that abound in social networks. These blog posts are often related to a specific interest or subject matter explicitly identified by the blog author. Though some blogging platforms allow users to interact on a limited basis — such as via comments, follower relationships, votes, or blogrolls (collections of links to related or otherwise notable blogs) — as a whole, these interactions tend to be much more localized, and their networked nature less explicit. A few well-known blogging platforms include Google’s Blogger, Yahoo’s Tumblr, LiveJournal, Medium, and WordPress.

Wikis and collaborative editing systems, such as Wikipedia, Basecamp, or Genius, allow users to create and edit articles, to-do lists, events, rich media such as images and videos, and a variety of other documents in shared contexts, and at least in some cases, in real-time. Though users are the driving force behind any collaborative effort, in these systems, the focus is on content and how users can help develop and curate those contents as an engaged, participatory community.

An array of rich media sharing platforms also exist which rely on user-contributed media to make up either a large portion or the entirety of their respective content bases. Some examples include

the video hosting and sharing services YouTube (owned by Google), Vimeo, Vine (from Twitter), and Justin.tv. Music and other auditory media can be shared through services like SoundCloud and MySpace. Image hosting and sharing services include Pinterest, Yahoo's Flickr, Google's Picasa, Imgur, 500px, Facebook's Instagram, and Snapchat (which has recently begun to expand into a more general online social network, through the deployment of new and broadened functionality).

Geolocation-based social services offer users the ability to share their location and "check-in" (an indication of one having visited a location of interest) activity, as well as to post comments or reviews, share pictures or other rich media, or to unlock rewards or other contents relating to a specific location. While many location-sharing services are built directly into or have been otherwise subsumed by larger social platforms, some yet exist as standalone ventures, such as Foursquare.

Link-sharing and social bookmarking services, which include, to various degrees, Reddit, Digg, Delicious, StumbleUpon, Slashdot, Hacker News, Fark, and others, offer as a primary feature the ability to share bookmarks or links to external content. These links may be associated with specific subjects, and are often able to be rated, saved, starred, flagged, or commented on by a larger community of viewers. In some instances, these platforms may allow text- or other direct media-based posts in addition to link submissions, though importantly, they often lack capabilities for networking among users, or place little emphasis on such functionality.

Social question answering platforms exist to help users locate relevant information based on questions they have or topics they want to learn more about. In these systems, other users with knowledge or expert experience relating to the subject matter in question can provide input to help steer the user along in their quest for information. Example providers within this domain include Quora, Stack Exchange, Ask MetaFilter, and Yahoo Answers.

Social shopping services span the gamut from online review portals such as Yelp, Epinions, and Angie's List, to deal sharing platforms like Slickdeals, Deals.Woot, FatWallet, and RetailMeNot, to actual user-driven marketplaces or online classifieds services, such as eBay, Etsy, and Craigslist, which distinguish themselves from traditional online shopping venues in part by allowing users to connect and market their goods or services to one another, directly.

Even outside of the range of services described above, social computing has had a dramatic impact. In some cases, whole other applications have been developed as a result of the growing popularity and reach of existing social platforms, such as reputation management or social analytics systems, including Netvibes and Klout; social media management systems like HootSuite and Twitter's TweetDeck; and community development or augmentation systems, including Disqus, Livefyre, and Ning, which allows customers to create their own social networks, tailored to a specific brand or interest.

Additionally, many specialized social services exist to address the needs of a specific niche or class of users, such as the widely used professional network, LinkedIn, enterprise social networks Yammer and Chatter (from Salesforce), or the social TV service, GetGlue, which provides "check-in" style functionality for television broadcasts. Still other services have been left outside of the scope of this review altogether, such as online podcasting and podcast sharing services, open source software collaboration systems, peer-to-peer (P2P) file sharing services, chat and video calling platforms, and more, if only for the sake of brevity.

It should be noted, too, that many sites that may not otherwise fit squarely into any of the categories outlined above have integrated a wide range of social computing features, such as comment systems, social voting or ranking systems, user networking functionality, social bookmarking or sharing links, customer reviews, or collaborative

filtering systems, such as Amazon's recommended product listings or Netflix's video recommendations system, which rely in part on the activities of other users to generate their product and video recommendations, respectively.

RESEARCH THEMES IN SOCIAL COMPUTING

Several existing works have already detailed many of the contemporary issues in social computing research (see, for example: Parameswaran & Whinston, 2007a; Parameswaran & Whinston, 2007b, Wang et al., 2007). Additional works have sought to classify the inherent themes of social computing research throughout the history of the field (e.g., Wang et al., 2014). In this section, we relay broad categories of contemporary research interest in social computing, offering specific examples of "hot spots" for researcher activity within each heading.

Engineering and Software Development

Engineering and software development comprise a crucial component of social computing, and although these research pursuits may seem more in alignment with the various reference disciplines of social computing, advances in social systems have often played a crucial role in shining a spotlight on engineering- and software development-related research interests.

Some examples of research issues within this theme include how best to represent networked relationships from an information storage and retrieval perspective; how to provide for the scalability needs of large, networked systems (including scaling data storage and retrieval facilities, information processing and session handling resources, content distribution, and so on); best practices and innovations in mining stream data or data at scale; load balancer design and optimization; optimal design and management of data

centers; how to implement and enforce access statutes relating to content visibility and shared resource ownership; how to detect anomalous user behaviors to prevent unauthorized access to user data, proprietary information, or intellectual property; the development of streamlined development processes and efficient team/project management capabilities; evaluation and selection of development methodologies; evaluations of feature testing and debugging practices; as well as various implementation details relating to specific social computing affordances, such as techniques for providing shared resource ownership, real-time collaboration, and granular privacy filtering mechanisms in shared contexts.

Social Psychology

Being inextricably intertwined with the social nature of human actors, social computing is also naturally concerned with issues stemming from its social psychology reference discipline, such as attitudes and change, social cognition, self and social identity, influence and reputation, interpersonal relationship development, and the wisdom of the crowd.

In addition, communications technologies have further highlighted more nascent areas of psychological interest, such as in determining the influence of mode of communication, sense of presence or social embedded-ness, and identity (including anonymity and pseudonymity) for a particular computer-mediated social interaction.

Researcher attention has also converged recently on evaluating the formation of online communities (for example, analyzing what conditions must exist to motivate the development of a community, or to procure involvement), as well as the long-term stability of online communities, and what factors play a part in maintaining the health and longevity of those communities. Participation itself is another dominant research interest in this context. For example, though it is widely accepted that the viability of a social application and its ability to establish communities

“depends on the willingness of the participants to share” (Nov and Wattal, 2009), motivations for participation may vary, and the same strategies for engaging one subset of users may not work for others. Some social studies also focus on investigating negative participant behavior, such as engaging in “trolling” (inciting), abusive, or criminal behaviors online. Studies in this area may examine the individual or collective propensity to offend, motivating factors for misconduct, or how best to moderate undesirable behaviors in online social communities.

Marketing and Design

Within the theme of marketing and design, social computing researchers may investigate the impact and motivators for virality (the rapid dissemination of contents or adoption of new services); consumer technology acceptance and adoption, and how this may influence the spread or use of a particular social platform across genders, age groups, locales, etc.; targeted marketing best practices; best practices for reputation management and brand development across social media platforms; user experience and human-computer interaction considerations, including best practices for optimizing for ease-of-use, readability, optimal click-through rates, and other factors across device types; how to maximize user engagement; and the use of design methods.

Social Computing and the Organization

As social computing has evolved and witnessed more mainstream adoption, it has become a significant technological cornerstone of the organization, as well. Research issues relating to organizations’ adoption and use of social computing systems include assessing social computing’s impact on organizational structure, the protection of intellectual property rights in systems of mass-scale distribution, the influence of social technologies on workplace productivity, organizational adoption of

social technologies, monitoring of social interactions, conflict resolution on social or collaborative systems, social media management, and others. Leonardi et al. (2013) provide a well-rounded account of social computing’s history, usage, and research issues in the enterprise context. R  th et al. (2012) have identified a number of obstacles to implementing social computing solutions within corporations, providing a list of recommendations or mediating actions to help ensure successful workplace adoption of such technologies.

Social Curation and Analysis

From an analytics perspective, large scale social computing platforms provide a wealth of potentially useful information made publicly available by their users. This has motivated research interests in natural language processing (NLP) and sentiment analysis to provide automated means of extracting meaning from user contents, estimating social capital (for example, influence or reputation metrics) for marketing purposes, knowledge mining, and data curation for separating the wheat from the chaff in automated tasks (such as identifying erroneous information or disambiguating subject matter in social question answering systems). In addition, personal analytics has recently emerged as a fledgling area of research interest in this area, seeking out means for quantifying personal data for evaluation or prediction tasks, as well as conducting automated knowledge extraction for the purpose of targeted marketing initiatives, catered content delivery, and other endeavors. Entirely new forms of social networking have even emerged around the idea of personal analytics, such as the web service, Gyroscope, which allows users to share monitored health and fitness metrics, app usage information, and more. The scale of these myriad forms of analysis, coupled with the immense availability of social data, has also spurred research interest in privacy and ethical considerations pertaining to social computing, in the same way that such concerns were previously expressed towards the

idea of ubiquitous computing (see, e.g., Bohn et al., 2005).

Clearly, the wide reach and diversity of social computing research issues offers this field as a noteworthy candidate for multidisciplinary or interdisciplinary studies, and one through which new knowledge discoveries may offer considerable reciprocal value to the various reference disciplines of the field.

FUTURE RESEARCH DIRECTIONS

While many of the emerging research themes in social computing have already been outlined in the previous section, there remain several areas of potential research interest that have, to this point, received comparatively little attention from the academic community. It is no mystery that we are moving toward a continuously more interconnected and mobile society. While there remain many challenges (whether technical, economic, cultural, or political in nature), researchers should look ahead to a time when these challenges are able to be resolved, or at least where they may loosen their restrictive hold on the progression of social computing technologies.

From a hardware perspective, we can expect continued advances in notable areas such as processing power and battery capacity. In addition, we can look forward to even greater coverage and throughput from wireless communications infrastructures, and fewer “dark spots” of wireless interconnectedness, even in regions that are as yet considered developing territories. In the course of this progression, it is important to consider the impact of such advancements in the present term, so that we may better prepare ourselves — as both the studiers and practitioners of social computing technologies — for the landscape we may soon be constituents of.

As mobile battery capacity continues to increase, it is not unlikely that the consumption of rich media (a typically battery-intensive activity)

will increase concomitantly. In addition, “always on” GPS-based location services will be much more feasible, along with more general wireless data transmissions, or sensor-based data collection activities. How might this new surge in location and data collection capabilities, as well as rich media consumption, alter the social computing landscape?

We’ve recently seen the development of many novel personal assistant technologies, such as Apple’s Siri, Google Now, Microsoft’s Cortana, and Evi. As systems such as these operate predominantly in the mobile application space, how will this new wealth of data augment their functionality? Will they become an increasingly prevalent force in our daily lives, perhaps going so far as to completely automate our scheduling and event planning activities, or managing social connections on our collective behalf? Perhaps remembering to purchase a birthday gift or to pick up flowers on an anniversary — for better or worse — will soon be but a memory, as these responsibilities are delegated to increasingly intelligent, socially-connected systems.

If we look at an even lower level, what new hardware devices might evolve as technologies with even the smallest of form factors develop more advanced capabilities? We’ve already witnessed several new developments in this area, such as smart watches or optical head-mounted displays (e.g., Google Glass), both of which boast at least moderately capable embedded computing platforms. When a device no larger than a marble offers more computing power than today’s high-end servers, coupled with sufficiently advanced battery life, what new applications and use cases for social computing technologies will unfold?

Lastly, in the more abstract sense, how will these things continue to alter how we operate as individuals and societies? This has certainly been a widely-discussed topic already, but when we look ahead at an increasingly global social footprint and sense of connectedness, will we witness only more of what we’ve seen already,

or will the impact change as social computing encompasses the daily lives of even more parts of the world and a more diverse array of cultures? Someday soon, it may well be the case that not a single person alive (barring the most extreme outliers) has existed in a time without advanced mobile communication devices. It could, in fact, be argued that we are still within a transitional time in the advancement of human capabilities. If so, what will this latest of “dark ages” look like through the eyes of our progeny, and how might they appear to us?

CONCLUSION

In this chapter, we’ve provided a concise and not overly technical overview of the field of social computing, so as to assist readers of various levels of expertise in becoming acquainted with the subject. In doing so, we have provided basic background information relating to the establishment of social computing as a field of academic and practitioner interest, defined social computing as it is today and may evolve in the future, provided an overview of a range of practical social computing applications, and outlined a number of research themes being actively investigated in the field.

Weiser (1999), in introducing his vision for 21st century computing, spoke of the idea of technology becoming so ingrained in everyday life that it seems to disappear from attention, entirely. In many ways, we find ourselves now entering the next stages of that evolution, where technology is no longer merely at home in our lives, but is indistinguishable from them, fundamentally reshaping our environments and decreasing our ability to demarcate how it is or is not influencing our collective behavior. As social computing continues to grow ever more ubiquitous, connected, and absorbed into even the most granular functions of our day-to-day existence, so too will it continue to take on new forms, and uncover new potential, owed to the efforts of practitioners and

academicians alike, who devote their energies to the upbringing of this young field.

KEY TERMS AND DEFINITIONS

Blog (Web Log): A medium for posting detailed text or rich media entries, often as part of a larger collection pertaining to some overarching subject or theme.

Check-In: A function for expressing a user's visiting of a physical location, or their participation in some event or occurrence, physical or otherwise.

Collaborative Filtering System: A system which evaluates the historic activity of its users in order to make predictions about the preferences of those users or others who are, by some criteria, viewed as being similar to them.

Peer-To-Peer: A connection existing directly from one user to another, with no intermediary.

Social Identity: How a user is perceived within a larger social community.

Social Network: A social computing application that allows users to establish friend or follower-type relationships with one another, and to exchange or broadcast text and rich media contents either directly or via aggregated timelines of activity.

Trolling: Incendiary behavior by users of a social system intending to incite outrage or otherwise evoke a negative response within a community.

Virality: The widespread propagation or adoption of new contents or services across an online community.

Ubiquitous Computing, Contactless Points, and Distributed Stores

Saverino Verteramo

University of Calabria, Italy

INTRODUCTION

Nowadays, retailing is subjected to constant changes due to the continuous advancements in technology (Pantano, 2014). In fact, the increasing computing capabilities, the mobile and wireless technologies improvements, as well as the development of flexible software architectures and automatic identification technologies support the ubiquitous access to data for both consumers and firms. As a consequence, these new systems modify the interface between clients and vendor, by providing new consumer-oriented services (Ngo and O’Cass, 2013; Pantano, 2014), as well as the customer behavior and corporate approach to retail process, by changing both the way customers access and consume the information, and the way firms and organizations reach clients and deliver the service (Kim, et al., 2009; Demirkan and Spohrer, 2014).

In this scenario, ubiquitous computing is supporting ubiquitous access to information for consumers and marketers, with emphasis on retail services (Pantano, 2013). It is based on the ubiquitous computing, which can be viewed as an extension of mobile computing characterized by portable accessing technologies (i.e. cameras, Location Based Service, Ubiquitous Sensor Network, etc.), always connected to a network, and linked to web-based multimedia content repositories that

adapt the provided contents according to users’ data (i.e. location, preferences, etc.) (Lin, et al., 2011). Therefore, these innovations are removing the boundaries of the physical space (Kourouthanassis et al., 2007; Bourlakis et al., 2009; Demirkan and Spohrer, 2014; Pantano, 2013; Pantano, 2014), while pushing retailers to redefine the traditional business model and practices. Similarly, a huge number of “contactless technologies” is emerging as the most promising direction for supporting retailing and shopping experience, by providing new modalities for automatic payment and self-checkout (Lai and Chuah, 2010). These are based on proximity sensor that allows payment without entering any pin. For these reasons, the number of contactless transactions is speeding up fast the payment process, increasing the convenience of shopping experience and reducing the queues. In fact, many retailers are soliciting users to adopt this system, such as McDonalds that offers a free drink on any menu purchased via contactless. For instance, MasterCard reports that the 10% of transactions made in Australia under \$100 is performed via contactless technologies, while VISA Europe reports more than 1 million of contactless purchases in August 2013 (VISA Europe, 2013).

The aim of this chapter is to provide a comprehensive view of the new retail competitive scenario, starting from the most innovative technologies in retail domain. Subsequently, it sheds

light on the possible consequences of these radical innovations in terms of store structure, and provides some indications for predicting the trends of the future (technology-enriched) shopping places.

BACKGROUND

As anticipated, the continuous progresses in information and communication technologies (ICT) impact on retail strategy and operations triggering the proliferation of new channels and new modalities through which customers may directly interact with firms. Due to the large amount of technological innovations, the necessity to classify them emerges as the starting point for a deep understanding of the current scenario. In this chapter, we propose a classification based on the functions of these systems for retail purposes as follows: (i) technologies for virtually trying the products, (ii) technologies for automatic product search, (iii) technologies for automatic payments, and (iv) full-service technologies (technologies integrating all these services).

Technologies for Virtually Trying Products

Current advances in 3D graphics and virtual reality tools offer novel and realistic interfaces that can be easily integrated in physical environments for enhancing the sensorial inputs and enriching consumers shopping experience (Bullinger et al., 2010). Augmented reality emerges from the integration of virtual reality, with emphasis on the most advanced graphics, in real contexts by enriching the human sensory perception with multimedia contents and information to the reality. (Papagiannidis et al, 2014). Hence, it includes a real-time view of the physical world enhanced (augmented) with virtual computer generated information, such as digital images or video stream, etc. (Azuma, 1997; Carmigniani et al., 2011).

The integration in retailing offers virtual mirrors, virtual fitting rooms and interacting shopping windows, which customers might experience by virtually trying the products through digital interfaces under the promise to save time while living a more exciting shopping experience (Dey and Sandor, 2014). In this direction, one of the most promising areas of research is the virtual garment try-on experience (or virtual fitting), which allow consumers to try clothes and evaluating the effect without really wearing them (Chen et al., 2011; Pereira et al., 2011; Wang et al., 2012).

Technologies for Automatic Product Search

Technologies included in this category support the search of a certain product throughout the store. They are especially exploited in the large department stores for helping consumers to easily find the favorite item (in terms of exact location including floor, area, etc.) without the direct assistance of a salesperson (Pantano and Timmermans, 2014).

RFID (Radio Frequency IDentification) is one of the first examples of contactless technology, consisting of an enriched version of the barcode. It is the most common technology used to identify and localize objects from a distance (Garfinkel and Rosenberg, 2006). In particular, it consists of a radio frequency transceiver (transmitter and receiver) attached to the item to be identified by a reader device (interrogator device) used to read the information stored on the tag. RFID tags are also used to improve the in-store security, to enhance the rapid checkout of consumers, and to manage the shelf-life of products (i.e. by evaluating in real-time the quantity of a certain product on the shelf).

QR Codes technology has become one of the most-used types of two-dimensional barcode. Developed in the automotive contest, it is currently used in a broader context, including both tracking for logistics purposes and convenience-oriented

applications aimed at enriching consumers shopping experience through smartphones.

Technologies for Automatic Payments

Contactless technologies support the spreading of mobile payments, by offering the shift from the traditional magnetic stripe or “Chip and Pin” to contactless cards, where tag brought into close proximity substitutes the card sweeping or insertion into the reader (and the subsequent request of PIN or authorization for the payment), with benefits for the financial transactions in terms of time saving and ease of process, and the consequent reduction of the queues. For these reasons, contactless payment is particularly important to retail settings where speed and convenience of payment are the basic elements of the success, such as fast food and kiosks. For instance, in the US market, contactless payment is an established method especially in the fast food, leisure and sport industries (Olsen, 2008).

The implementation of these technologies creates benefits for both customers and retailers. Consequently, innovative ways for transactions at the point-of-sale are proliferating and mobile payments are one of the most investigated technologies in retail industry from a both scholars and practitioners perspective (Pantano and Viasone, 2015).

The continuous research in wireless technologies provides further systems such as NFC (Near Field Communication) and beacons, which are driving mobile phones to facilitate the access execution of several monetary transactions and are successfully employed for automatic mobile payments (Olsen, 2008). In particular, beacons consist of small and low cost transmitting devices, which do not require a limited distance between the devices to set the transaction.

These devices might share data via Bluetooth connections, such as specific deals or product information, while tracking their location/route within the store (in-store location). For instance,

after downloading the mobile app, consumers may receive customized deals or special offers when they are within 50 meters of a specific shelf or mannequin. From a corporate perspective, retailers would obtain information about consumers behaviour such as time spent in a certain area of the stores, accessed information, consumers profile, etc...

Full-Service Technologies

The last group of technologies includes those that support the delivering of more services, including both product search and payment. Ubiquitous stores are a meaningful example of these technologies offering a “full-service” for consumers (Pantano, 2013). The term ubiquitous computing was created to describe the ubiquity of information technology and computer power that pervade almost all everyday objects (Pantano, 2013).

Communication technologies, and particularly mobile applications, can be considered as the fundamentals of the ubiquitous computing environment. From the systematic integration of the above mentioned technologies, the features of this new scenario arise as follows: (i) embedding of computer hardware and software in other equipment and objects; (ii) providing constant network accessibility and connectivity by user’s mobile device (e.g. via wireless, Bluetooth, etc.); (iii) supporting users through information services anytime and anywhere (accessing to the requested information via embedded input devices such as GPS or camera); (iv) context awareness and adaptation of the system to current information requirements (i.e. the system replies according to consumers’ location); (v) automatic recognizing and autonomous processing of repetitive tasks without user intervention (Kurkovski, 2005; Gabriel et al., 2006; Lin et al., 2011).

In a ubiquitous environment users are connected anytime and anywhere, automatically sharing information and receiving services or other contents related to the currently experienced context. Indeed one of the goals of such environ-

ment is to capture, use and manage a huge amount of information, on which companies can built up their competitive advantage with accessible, reliable, and relevant information (Turner, 1978).

Ubiquitous computing improves considerably companies' access to information by allowing them to acquire updated data at anytime and anywhere from their customers, by changing the interaction between businesses and customers in both time and space. Furthermore, information captured from the multiple interactions with customers can create value and increase transactions through the enhanced possibility to provide customized service and sell complementary items as well as be exploited for the development of more effective marketing strategies. Such information can also reduce the costs of subsequent transactions through more efficient communications programs and delivery methods (Kim et al., 2009). For these reasons, it can be successfully applied at the context of retailing, creating a new environment for selling and purchasing: ubiquitous retailing (Pantano, 2013). Within these settings, the products displayed appear as virtual full-size reconstructions, associated with a QR code, that consumers may scan by focusing a mobile camera in order to visualize the relevant information and have the possibility to collect them in their virtual baskets. After the effective order and mobile payment, purchases are delivered directly at home. Recent applications of "u-stores" can be found particularly in grocery industry, placed inside bus/tube stops for shopping daily food and beverage (Pantano, 2013). Thus, even perishable goods can be sold without a need for refrigeration within the store. Examples are Sorli Discau and Tesco "HomePlus" virtual stores, located respectively in Barcelona and Seoul, with the goal to turn waiting time into shopping time in consumers daily life.

MAIN FOCUS OF THE ARTICLE

The technologies presented in the previous section largely impact the traditional retailing activities.

While a problem of the traditional retail settings relies on the physical boundaries of the store (i.e. fixed and limited space), the new technologies allow consumers to buy anytime anywhere, without any need of further assistance. Hence, their main limit relies on the technological boundaries, due to the connection availability and the technological adequacy of the device used by the customer.

Therefore, ubiquitous computing and contactless technologies offer the possibility to totally reconsider the physical boundaries of the traditional stores for moving towards a new concept of store.

In fact, if a traditional point of sale is limited to the store location, spatial dimensions and opening hours, the new stores are not related to a specific location but *distributed*, in terms of access anytime and anywhere within an area enriched with the above mentioned technologies. As a consequence, these new stores are based on the higher level of technology integration and accessibility to products and related information for consumers.

Starting from Diamond's (2010) idea that retailer should be always ready to satisfy consumers' expectations, the traditional store concept breaks down as these technologies allow vendors to satisfy consumer's need as soon as it emerges through the high internet connectivity. For instance, if a consumer shows the need to buy a new bag while waiting for entering a theatre, he/she is able to find, compare and buy the favored items that retailer will delivery within an acceptable amount of time. Moreover, retailers might propose consumers new deals and offers while they are in queue for entering a certain exhibition. Likewise, a customized offer can be accessed by the in-car Internet connection, matching the user exact position with his/her product preferences (i.e. based on past purchases), personal profile (e.g. age, gender, education, address, etc.) and behaviour (car routes and destinations, etc.). This prompts consumer to be able to buy and retailer to sell continuously.

As a measure of the consequences of the new technology-based store, we could consider the spatial dimension, which synthetizes the changes

in physical surface triggered by the adoption of the advanced technologies and the idea of *distributed store* (in other words it represents the space that the innovation requires within the store for the correct technology access/functioning).

As emerged from previous sections, we identified few categories of technological innovations that are changing retail process. These emerging technologies tend to create a new store concept based on a mobile access to store, with consequences on the drastic reduction (or even *absence*) of the physical store floor (see ubiquitous computing), which might be accessed directly from consumer's own smart phone, without the need of a physical support tool in the point of sale. In fact, the ubiquitous store overcomes the physical surface of the traditional store, which is replaced by urban areas such tube stops, representing the current innovation frontier for retailing.

Therefore, the progresses in technologies provide new tools for moving traditional fixed stores towards a mobile and ubiquitous dimension, while the relevance of the technology in the store increases.

As anticipated, contactless technologies, RFID systems, and AR applications have been introduced as an added tool with a limited relevance into the physical store. In opposite, the stores built on ubiquitous and mobile computing do not allocate

any physical space in the “traditional store” (even if some stores can advise consumers about the available apps with posters, etc.), which might even take place within urban areas. This emerging store, the distributed one, is built on a software virtually reproducing the store, by presenting a new kind of point of sale that radically redefines the space and time of retailing, and modifies the role of the actors involved in the process (Evans and Hu, 2007; Kourouthanassis et al., 2007; Bourlakis et al., 2009; Walter et al., 2012; Pantano and Viassone, 2015).

SOLUTIONS AND RECOMMENDATIONS

To provide a comprehensive view of the existing retail scenario in order to better predict the future evolution, it is possible to summarize the possible retail scenario on the basis of technology progress/usage and related boundaries, by considering the actual shift from the physical boundaries to the technological ones. To this end, Figure 1 synthesizes the emerging retail landscape, where traditional stores are characterized by both a low level of technological integration and physical boundaries (i.e. the store in a fixed location and fixed opening hours) (down left quadrant).

Figure 1. From traditional to distributed stores

The subsequent introduction of technologies pushes towards a new enriched store, where the technology acts as support tool for consumers by delivering enriched services (i.e. stores offering interactive displays for accessing information, or automatic cash desks for self-checkout), thus it is still related to a fixed store location and fixed opening hours (up-left quadrant). The second quadrant of the matrix (up-right) represents a scenario characterized by a high access to the technology, where the extended usage of ubiquitous computing and contactless technologies allow consumers to purchase anytime and anywhere in a sort of “distributed store”. Thus, the main features of this new concept of store include (i) accessibility anytime (24/7) and anywhere within specific technology-enriched areas where Wi-Fi internet connection is available; (ii) enhanced and customized consumer services (these stores offer a larger service portfolio if compared to the traditional ones); and (iii) interactive and customizable products displaying (i.e. consumers might visualize only the favored item, rotate the product and change perspective, etc.).

In the one hand, the new retail settings enlarge the traditional boundaries of the fixed points of sale; whereas in the other one, they are limited by the availability and performance of these technologies, which characterize the new store boundaries.

As shown in the last quadrant of the matrix, due to the dichotomy of “no technological progress” and “technological boundaries”, a scenario characterized by a limited technology progress and technological barriers is not actually conceivable.

FUTURE RESEARCH DIRECTIONS

The development of an effective distributed retailing scenario is both a short and long-term program requiring well thought-out roadmaps, which retailers should start exploiting by deeply understanding their capacity to absorb technological innovation in terms of new business models, reconfiguration of internal resources (both financial and human

ones) and channel strategies. They should also deeply re-design the consumer experience taking place out of the traditional point of sale. Hence, new studies should focus on these elements, by providing new frameworks for understanding the phenomenon and new measures for evaluating the best strategy to adopt. Since this study is explorative in nature, it would be beneficial to complement it with further investigations concerning the shopping experience emerging from a technology-enriched retail environment, in order to identify the new dynamics of consumer behaviour and the evolution of the shopping habits.

Therefore, a set of new questions to be addressed emerges for the definition of more efficient marketing and retail strategies:

- To what extent will the technological progress for retailing be feasible and sustainable?
- How can retailers identify the best scenario for competing and the right moment for innovating?
- What would the consequences of a technology failure be for the retail process?

CONCLUSION

This chapter shows the extent to which the recent advances in technology provide an increasing integration of computing in consumers shopping activities through a pervasive penetration, starting from Evans and Hu (2006) reflections on the spread of pervasive and ubiquitous systems. These technologies represent the further steps of traditional point of sale development into an innovative shopping environment.

Past studies anticipated the trend towards ubiquitous stores based on a high level of connectivity and extensive usage of mobile devices (Kourouthanassis et al., 2007; Bourlakis et al., 2009; Pantano, 2013; Blazquez, 2014; Pantano, 2014). Our chapter extends these studies by exploiting the concept of distributed store, which

overcomes the conventional physical boundaries in a sort of evolution of the traditional stores. In fact, within these new retail settings, boundaries are no longer physical or temporal but technological: the implementation and success of distributed stores is strictly connected to the access and integration of the advanced technology. This evolution provides new benefits for customers as well as opportunities for practitioners. In this way, consumer experience and store concept are redefined, where the shopping experience begins before the consumer enters the traditional store and continues after the purchase, accompanying him/her during the various activities of daily life.

KEY TERMS AND DEFINITIONS

Beacon: Small and low cost transmitting device, which do not require a limited distance between the devices to set the transaction. This device might share data via Bluetooth connections, such as specific deals or product information, while tracking consumers location/route within the store (in-store location).

Contactless Technologies: New technologies based on proximity sensor that allows payment without providing any pin or signature.

Distributed Store: New stores not related to a specific location but distributed, in terms of access anytime and anywhere within an area enriched with contactless and ubiquitous technologies.

Near Field Communication (NFC): Technology providing mobile devices with wireless two-way short-range connectivity up to a maximum of 10 cm.

Quick Response Codes (QR): Bidimensional barcode able to augment the reality with contents and information by scanning it with a smartphone camera.

Radio Frequency Identification (RFID): One of the first examples of contactless technology, consisting of a modern version of the barcode. It is based on a radio frequency transceiver (transmitter and receiver) attached to the item to be identified by a reader device (interrogator device) used to read the information stored on the tag.

Ubiquitous Computing: A sort of extension of mobile computing based on the portable accessing technologies (i.e. cameras, Location Based Service, Ubiquitous Sensor Network, etc.), always connected to a network, and linked to web-based multimedia content repositories that adapt the provided contents according to users' characteristics (i.e. location) (Lin, et al., 2011).

Climate Change as a Driving Force on Urban Energy Consumption Patterns

Mostafa Jafari

Agricultural Research Education and Extension Organization (AREEO), Iran

Pete Smith

University of Aberdeen, UK

INTRODUCTION

Climate change has impacted on Iranian natural ecosystems and urban area in various ways (Jafari, 2010). Climatic factors, including temperature, precipitation and humidity have changed in pattern in recent decades (Jafari, 2011). Changes in temperature and precipitation patterns could have impacts on urban areas as well as forests, rangelands and desert ecosystems (Jafari, 2008a). Changing climate patterns and increasing pollution may lead to changed production patterns (Jafari, 2012a) or may increase pressure on the environment (Jafari, 2012b). Environmental sustainability among two others, Energy security and Energy equity are the world energy trilemma (Wyman, 2013). Attempts to mitigate climate change need to be done without compromising food security or environmental goals (Smith *et al.*, 2013).

In this paper, we present a case study, from Rasht City in Iran, to show how changing climate is expected to have influenced energy consumption patterns. We use climatic data to determine the number of days when heating and cooling demands occurs, using Heating Degree Days (HDDs) and Cooling Degree Days (CDDs). These are based on daily temperature observations, with each month having at least 25 records and no less than 15 years of data (Anonymous, 2008a). HDD and CDD, which indicate the level of comfort, are based on the average daily temperature which is taken as

the mean of maximum and minimum daily temperature (the National Oceanic and Atmospheric Administration – US NOAA).

If the average daily temperature falls below comfort levels, heating is required and if it is above comfort levels, cooling is required. HDD is an index of the energy demand to heat buildings, and an analogous index for the energy demand for cooling is represented by cooling degree days (Sivak, 2013). The HDDs or CDDs are determined by the difference between the average daily temperature and the BASE (comfort level) temperature. The BASE values used are 12 and 18 degrees Celsius for heating and 18 and 24 degrees Celsius for cooling (Anonymous, 2008a). In this case, base degrees for heating are 18°C and for cooling is 21°C. For example, if heating is being considered to a temperature BASE of 18 degrees, and the average daily temperature for a particular location was 14 degrees, then heating equivalent to 4 degrees or 4 HDDs would be required to maintain a temperature of 18 degrees for that day. However if the average daily temperature was 20 degrees then no heating would be required, so the number of HDDs for that day would be zero. If cooling is being considered to a temperature BASE of 21 degrees, and if the average temperature for a day was 27 degrees, then cooling equivalent to 6 degrees or 6 CDDs would be required to maintain a temperature of 21 degrees for that day. However if the average temperature was 20

degrees, then no cooling would be required, so the number of CDDs for that day would be zero. Similar estimates have been made in the USA, mainly using the Fahrenheit temperature scale (Anonymous, 2008c; Anonymous, 2008d). Costs are calculated by multiplying the HDD or CDD by the average daily cost of heating or cooling (Anonymous, 2008e).

HDD can be added over periods of time to provide a rough estimate of seasonal heating requirements. In the course of a heating season, for example, the number of HDD for New York City is 5,050 whereas that for Barrow, Alaska is 19,990. Thus, one can say that, for a given home of similar structure and insulation, around four times the energy would be required to heat the home in Barrow than in New York. Likewise, a similar home in Los Angeles, California, where heating degree days for the heating season are

2,020, it would require around two fifths the energy required to heat the house in New York City (Anonymous, 2012).

The following figures (Figure 1) show some of the energy-based driving forces within the scenarios that are particularly important to us. The world faces a range of futures, with the possibility that energy intensity (efficiency) might improve by a factor of eight by 2100: primary energy use rise initially under all scenarios, then decrease slightly or increase by a factor of 3.3: coal use may increase slightly, or almost disappear completely: and alternative, non-carbon, energy sources (including non-commercial) may halve in importance or become the norm. The question is which future will we choose? (Coley, 2008).

Our civilization and our standard of living depend on an adequate supply of energy. We need energy to light and heat our homes, to cook

Figure 1. Energy-based driving forces of SRES illustrative scenarios, A1F1, A1B, A1T, A2, B1, B2: 1980-2100 [data from IPCC 00]; energy intensity (MJ/US\$): top left; primary energy use (EJ/ annum): top right; coal: % share of primary energy: down left; sustainable: % share of primary energy: down right
Source: adapted from data in Emission scenarios: summary for policy makers, IPCC, 2000, www.ipcc.ch/pub/synergy.htm

our food, to drive our transport and power our communications and to provide the motive force that drives the factories. Without energy all this would be impossible on the scale needed, and our civilization would soon collapse. Our dependence on energy is strikingly illustrated by the connection between average life expectancy and energy consumption (Hodgson, 2010). Climate is one of the determining features of civilization, so any change in the climate can have momentous consequences (Hodgson, 2010). The importance of climate for civilization is further discussed by Hodgson (2010).

BACKGROUND

An attempt has made to evaluate climate change impact on different sectors including natural ecosystem and urban areas. Outcomes obtain from research project in urban zone which is near to forest area may help to recognized its impact on natural ecosystem in one way or another (Jafari, 2013). According to the research outcome, consideration and analysis on Energy Consumption Pattern and GDP in global level in different developed and developing countries it has been proved that, GDP and Energy Consumption of developing countries are increasing exponentially, while GDP and Energy Consumption of developed countries are increasing linearly (Akhter Hossain, 2012).

ENERGY CONSUMPTION PATTERN

Energy consumption patterns have changed in urban environments during the last few decades. Climate and environmental changes can be considered as one of the main driving forces for the changing pattern. Climate change has impacted on Iranian natural ecosystems and urban area in various ways. Climatic factors, including temperature, precipitation and humidity have changed in

pattern in recent decades. Changes in temperature and precipitation patterns could have impacts on urban areas as well as forests, rangelands and desert ecosystems. Changing climate patterns and increasing pollution may lead to changed production patterns or may increase pressure on the environment. Environmental sustainability among two others, Energy security and Energy equity are the world energy trilemma. Attempts to mitigate climate change need to be done without compromising food security or environmental goals. This research investigated the phenomenon in Rasht city, Iran. HDD, in cases where temperatures are below 18°C, and CDD, in cases where temperatures are above 21°C, were used as energy consumption indices. During the last half century, mean annual temperatures have increased and as a consequence, CDD in the warm season have increased sharply. In the same time slice, HDD, even in the cool and cold season have declined steadily. This present work shows that energy consumption patterns have increased sharply, and with available projection scenarios, is projected to increase more rapidly, leading to higher energy costs.

STUDY METHOD

Electricity Energy and Heating Oil

Site-specific total electricity energy and heating oil consumption for individual residences show very high correlation with national weather temperature data when transformed to heating degree days (Quayle & Diaz, 1979). In this investigation, past climate conditions for temperature in Rasht City were considered. Energy demand for climate control was analyzed for Rasht city. The relevant parameters, climatological deviations from the desired indoor, were analyzed (Sivak, 2013). HDD, in cases where temperatures are below 18°C, and CDD, in cases where temperatures are

above 21°C, were used as energy consumption indices. Heating degree days and cooling degree days were analyzed (Jafari, 2013).

Location

Rasht is situated on the western part of the Albourz Mountain Range in the North West of Iran. The location of the study area is shown in Figure 2.

Temperature

Changing trends of temperature and precipitation in the last fifty years of the Caspian region have been investigated (Jafari, 2008a). In Rasht City, in the last 49 years (ended by 2005) precipitation increased by 56.4 mm and mean temperature increased by 1.28°C. Minimum temperature

increased by 2.45°C and maximum temperature by 0.08°C.

Past Climate Changes in Rasht

Past climate conditions for temperature in the region were analyzed in synoptic (49 years, 1956-2005) and climatology (Pasikhan climatology station which is nearest station to Rasht, 22 years, 1983-2005) stations. Two important factors, HDD and CDD, in Rasht, were considered. Mean annual daily temperature ($15 \pm 0.02^\circ\text{C}$) (1.28°C increase) and mean annual minimum ($10 \pm 0.05^\circ\text{C}$) (2.45°C increase) and maximum ($20 \pm 0.001^\circ\text{C}$) (0.08°C increase) temperatures have increased (Jafari 2008a). The HDD trend decreased in the last 49 years ($1652 \rightarrow 1470.7$) (Figures 3a and 3b), while at the same time, CDD has increased sharply (298

Figure 2. Study area location

Figure 3. Rasht synoptic station, 1956 – 2005, total monthly mean: a) mean heating degrees days °C (based upon 18°C); b) linear trend of mean heating degrees days, °C; c) mean cooling degrees days, °C (based upon 21°C); d) linear trend of mean cooling degrees days, °C

→ 490) (Figures 3d and 3c), indicating a warming trend in the Rasht region.

Investigation on Climate Change Projections in Rasht

Based on IPCC data and models in global scale and national data and information, downscaling maps at national and regional scales (Figure 4) have been produced (Anonymous, 2008b). Temperature in study area of Rasht is projected to increase between 1.2 to 1.4°C. Mean temperature of Gilan province for the time slice of 1976-2005 was about 16.2°C, and is projected to increase by 1.3°C, to reach to 17.5°C for the period of 2010-2039. Based on the same results, projections for the future, the number of hot days in Rasht region will increase by

between 11-20 days, and the number of freezing days will decrease by between -11 and -8 days.

RESULTS

Heating Degree Days (HDD) and Cooling Degree Days (CDD)

In the Rasht case study, total monthly heating degrees recorded in the winter season reached 341.3 degrees of centigrade (January) which is about 11.37 degrees per day (Figure 3a). In the same period, cooling degrees was 0.1 (Figure 3c).

Total monthly cooling degrees recorded in the summer season reached 132.2 degrees of centigrade (July) which is about 4.40 degrees per day

Figure 4. Distribution of mean temperature differences comparing 2010-2039 with 1976-2005 according to the downscaling of ECHO-G model outputs
Source: Anonymous, 2008b

(Figure 3c). In the same period heating degree is about zero (Figure 3a).

The trend in HDD has decreased in last 49 years ($1652 \rightarrow 1470.7$) (Figures 3a and 3b), while in the same period CCD has increased at a sharper rate ($298 \rightarrow 489.7$) (Figures 3c and 3d). These factors certify the warming trend in the Rasht region.

Total annual heating degrees in years 1956 in Rasht station was 1652 degrees of centigrade (Figure 3b) and total annual cooling degrees was recorded as 298 degrees of centigrade (Figure 3d). During the 49 years between 1956 and 2005, the trend of mean annual temperature increased from 15°C by about 0.02°C to 15.02°C

This warming caused a decrease of total annual heating degrees by about 181.3 degrees of centigrade per year down to total annual of 1470.7°C (Figure 3b). Total annual cooling degrees increased by about 191.7°C per year up to total annual of 489.7°C (Figure 3d).

Decrease of 181.3°C per year of heating degrees and increase of 191.7°C of cooling degrees gives a difference of total of 10.4°C ($191.7 - 181.3 = 10.4^{\circ}\text{C}$) of extra energy consumption over the 49 year period.

Differences of HDD and CDD in year 1956 ($1652 - 298 = 1354$) and year 2005 ($1470.7 - 489.7 =$

981) shows about 373 degrees ($1354 - 981 = 373$), which is large.

The price of weather derivatives traded in the summer is based on an index made up of monthly CDD and HDD values. The settlement price for a weather futures contract is calculated by summing a month's CDD and HDD values and multiplying by \$20.

$$\text{HDD monthly cost} = \text{HDD} \times 30 \text{ (days of month)} \times 20 \text{ US\$}$$

In the Rasht case study a difference of annual total of 10.4°C calculated for an energy saving over 49 years' time. If we want to calculate cost as a rate of \$20 similar to USA conditions, after converting Celsius to Fahrenheit, it would be about \$374.4 as follow:

$$10.4 \times 9/5 = 18.72$$

$$18.72 \times \$20 = \$374.4$$

Temperature Changes

Based on recorded data in synoptic station, in Rasht during last forty-nine years, daily maximum (0.08°C), minimum (2.45°C) and mean (1.18°C) of temperature have increased.

Annual HDD with a base temperature of 18°C have reduced in the last 49 years (Figure 5e). HDD in January, which is a cold month, also slightly reduced. During the same period, annual CDD increased sharply (Figure 5f). CDD in July, August and September, which are warm months, also sharply increased (Figure 5d).

In Rasht City, total monthly heating degrees recorded in the winter season reached 341.3°C (January) which is about 11.4°C per day (Figure 3a). During the same period, cooling degrees were 0.1 (Figure 3c).

Total monthly cooling degrees recorded in the summer season reached 132.2°C (July) which is about 4.4°C per day (Figure 3c). During the same period, heating degrees were close to zero (Figure 3a).

SOLUTIONS AND RECOMMENDATIONS

Research work outcome on climate change impact on energy consumption pattern could help to plan better an adaptation action program.

It is a need to enhance much more research projects to consider climate change impact on natural resources including forest and firewood consumption.

FUTURE RESEARCH DIRECTIONS

As it has been mentioned earlier, main field of research project should be identified for consideration of climate change impact on different sector in related to the energy consumption.

One direction is cooling and heating energy consumptions and other direction is using biomass as energy resources and it comparing with fossil fuel consumptions.

CONCLUSION

Climate change is driven by the cumulative amount of GHGs emitted to the atmosphere (Meinshausen, *et al.*, 2009; Solomon *et al.*, 2010), in particular of long-lived species such as carbon dioxide (CO_2) (Huber & Knutti, 2012). Therefore, to halt anthropogenic climate change, global GHG emissions need to be reduced to virtually zero in the long term (Matthews & Caldeira, 2008). Achieving this will require massive transformations of all GHG-emitting sectors. Given that the global energy system (which supplies fuels and electricity to the residential/commercial, industrial and transportation end-use sectors) is currently responsible for about 80% of global CO_2 emissions (RCP Database, 2009; Boden *et al.*, 2012), transformations in this sector will be essential for realizing a low-carbon future. Moreover, the need for transformational change in the energy system has also been advocated for other important reasons, for instance to spur sustain-

Figure 5. Rasht synoptic station, 1956–2005, monthly and annual total HDD ($^{\circ}\text{C}$, base 18°C) and CDD ($^{\circ}\text{C}$ base 21°C): a) HDD in January, b) CDD in January, c) HDD in August, d) CDD in August, $^{\circ}\text{C}$, e) HDD for total annual, and f) CDD for total annual

able development or to improve the well-being of the impoverished billions in our society who lack regular access to modern forms of energy to meet their basic needs. From this perspective, we look at how energy-related targets fostering the abovementioned objectives would, or would not, be consistent with global climate protection (Rogelj *et al.*, 2013).

Mean annual temperature and even minimum temperature in last half century in Rash city has

increased (Jafari, 2008a), Table 1). Projections for future temperature changes in Rasht are mainly documented for increasing temperature and the extent of temperature increase varies by scenario (Jafari, 2012c).

The data provided by Energy in Focus, BP Statistical Review of World Energy, BP Plc, 2004, bp.distributionservices@bp.com, and adapted by Coley, (2008) shows how energy is spilt across the world. Obvious inequalities can be observed in

Figure 6. Rasht synoptic station, 1956 – 2005, annual total HDD ($^{\circ}\text{C}$, base 18°C) (top), CDD ($^{\circ}\text{C}$ base 21°C) (bottom)

how the world's primary energy is shared out, with North America (mainly the USA) using almost ten times more primary energy than the whole of Africa. This point is re-emphasized if we divide national primary energy use by national population, to give the energy use per capita (Figure 7). Much of the world is seen to use less than 63 GJ (1.5 Toe) (see end note) per capita per annum, whereas others use many times this (Coley, 2008). The annual primary energy consumption per capita (toe) (ENE, 2004) for Iran is in the range of 1.5-3, which in the development process, may increase.

As reported by National Iranian Oil Co. (NIOC 2007), in comparison of years 2006 and 2007, consumption of white oil (petroleum) has decreased by – 5.7%. This decrease may be described of effect of warming as well as subsidy payment

policy (Table 1, data obtained from NIOC (2007) and modified by authors).

Rasht city, according to the IPCC assessments report, is located in both Central Asia and West Asia sub-regions (Cruz *et al.*, 2007). Based on the projection for Central Asia sub-region, the region will face with higher degrees of temperature change. Downscaled projections in local level project that Gilan province as a whole will have a higher degree of temperature change than the western part of the province. Westwards into the mountainous area, a reduction in temperature is projected. Downscaling and projection of seasonal extreme daily precipitation has been studied elsewhere (Wang & Zhang, 2008).

Based upon mean monthly temperature changes in Rasht city, Jan. & Feb. were recorded

Figure 7. Annual primary energy consumption per capita (toe)

Source: Data obtained from NIOC (2007) and modified by authors

as coldest months and July & Aug. were recorded as warmest months (Figure 8 – top).

Monthly mean HDD and CDD changes are in high correlation with temperature changes pattern (Figure 8 – middle).

Marginal plot of annual total CDD vs HDD presents distributed dots as normal form for HDD, but for CDD is presented a little abnormality, which may refer to changing and increasing pattern of temperature (Figure 8 – bottom).

The amount of monthly and annual total of HDD (mean= 1556 Figure 9 bottom) are much higher than CDD (mean=400 Figure 9 top) in the investigated area. Even though, annual total HDD

and CDD have a negative correlation (Pearson correlation = - 0.493; $p < 0.001$).

HDD declines only a little and steadily ($R^2 = 0.062$ Figure 3b, $p = 0.099$ Figure 9 bottom), but CDD increases sharply during the same time slice ($R^2 = 0.427$ Figure 3d, $p = 0.813$ Figure 9 top). This means that the energy consumption pattern is expected to have increased sharply, and is expected to increase more rapidly in the future, which will result in increased costs.

Energy consumption for heating and cooling are driven by climate factors such as temperature, and is expected to change with a changing climate elements. Energy optimization solutions should

Figure 8. Recorded mean monthly temperature changes in Rasht city (top), Rasht synoptic station, 1956 – 2005, CDD (base 21°C) and HDD (base 18°C) for mean months for 50 years (middle), and marginal plot of annual total of CDD and HDD for 50 years (bottom)

Figure 9. Rasht synoptic station, 1956 – 2005, probability plot of annual total of CDD (base 21°C) (top), and HDD (base 18°C) (bottom)

be considered, as an important energy related issue. It has been investigated in Nigeria at country level (Anayochukwu & Ndubueze, 2012). Results obtained by the Sivak (2013), in USA indicate that climate control in Minneapolis (the coldest large metropolitan area in the US) is about 3.5 times

as energy demanding as in Miami (the warmest large metropolitan area in the US). This finding suggests that, in the US, living in cold climates is more energy demanding than living in hot climates (Sivak, 2013).

Heating degrees, cooling degrees are factors which impact on energy consumptions and these have changed, and are projected to change further in the future in Rasht City, unless mitigated by improved building energy performance, as suggested for Greece (Maleviti 2012). Heating and cooling energy demands have changed in Rasht by 10.4°C between 1956 and 2005, representing an annual extra cost of ~\$374, calculated based upon US daily costs for heating and cooling.

KEY TERMS AND DEFINITIONS

Cooling Degree Days (CDD): If the average daily temperature is above comfort levels, cooling is required. An analogous index for the energy demand for cooling is represented by CDD (Sivak, 2013). CDDs are based on daily temperature observations, with each month having at least 25 records and no less than 15 years of data (Anonymous, 2008a). CDD, which indicate the level of comfort,

are based on the average daily temperature which is taken as the mean of maximum and minimum daily temperature.

Energy Consumption Pattern: The way and total use of energy may be defined as its pattern. In general energy is classified into two main groups: renewable and non-renewable. Renewable energy is the cleanest sources of energy and non-renewable sources are not environmental friendly source of energy. According to (Akhter Hossain, 2012) GDP and energy consumption of developing countries are increasing exponentially, whereas GDP and energy consumption of developed countries are increasing linearly.

Heating Degree Days (HDD): If the average daily temperature falls below comfort levels, heating is required. HDD is an index of the energy demand to heat buildings (Sivak, 2013). HDDs are based on daily temperature observations, with each month having at least 25 records and no less than 15 years of data (Anonymous, 2008a). HDD, which indicate the level of comfort, are based on the average daily temperature which is taken as the mean of maximum and minimum daily temperature.

APPENDIX

Although the joule will be our standard unit, the importance of oil is such that the energy industry more often uses tonnes-of-oil-equivalent (toe). This is the energy content of one tonne of oil, i.e. 42 billion joules ($= 42 \times 10^9 \text{ J} = 42 \text{ GJ}$). (Coley, 2008).

Table 2. Common Energy Units

Unit	Pronunciation	Equivalence	Notes
kWh	kWh	$1 \text{ kWh} = 3.6 \times 10^6 \text{ J}$	Energy used by a single-bar electric fire left on for one hour
ft.	lb foot-pound	$1 \text{ ft.lb} = 1.356 \text{ J}$	Energy required to raise one pound in weight ($\approx 0.45 \text{ kg}$) by one foot ($\approx 0.3 \text{ m}$)
cal	calorie	$1 \text{ cal} = 4.19 \text{ J}$	Energy required to heat 1 g of water 1°C (at atmospheric pressure)
kcal or Cal	kilo-calorie	$1 \text{ Cal} = 4.19 \text{ kJ}$	Unit used by the food industry and easily confused with the cal
Therm	therm	$1 \text{ therm} = 100\,000 \text{ BTU}$	
BTU	British thermal unit	$1 \text{ BTU} = 1055 \text{ J}$	
Toe	tonne of oil equivalent	$1 \text{ toe} = 42 \text{ GJ}$	

Determination of Urban Growth by the Night-Time Images

Emre Yücer

Erzincan University, Turkey

Arzu Erener

Kocaeli University, Turkey

INTRODUCTION

Urbanization in Turkey and the world has continued to increase especially in the last 30 years. For developing countries, urbanization is a necessary phenomenon, especially in terms of the sustainability of urban growth. However, this growth must be controlled and in a planned manner, otherwise it could lead to many environmental problems. Therefore, urban areas, having a dynamic structure, should be monitored regularly and identified. Adequately accurate current data, which changes temporally and enables to monitor urban development and land use at regular intervals, are needed. Remote sensing technology is one of the most preferred methods in recent years to determine the urban areas developing fast and dynamically.

Within the scope of this study, using night-time images integrated with GIS, the spatial extent of urban areas in Turkey was identified and the methods used in the identification of the urban areas were compared. To determine the urban size of the cities in Turkey, DMSP-OLS (US Air Force Meteorological Satellite Program (Defense Meteorological Satellite Program) - Operational Line Scan System (Operational Linescan System) night-time images belonging to 2010 were used. While determining the urban size from night-time images, two different image analysis methods, object-based and pixel-based, were used. Object-based image analysis method involves image segmentation and pixel-based classification method involves natural breaks and Otsu method. By

comparing the results obtained through these three methods, the method that gives the most accurate urban area size has been determined. Through the comparison of these methods' features used in the determination of the urban areas, the differences, advantages, and disadvantages of these methods have been revealed.

BACKGROUND

Urbanization is quickly increasing in the world and according to data of the United Nations Population Fund it is estimated that the world's population will be 12 billion by 2050, 80% of this population will be living in cities. In our country where an intensely urban migration from villages has been observed, there has been a clear increase in the urban areas. The effects of this increase occurring in urban areas on the social, economic and cultural characteristics of a city and population are inevitable.

Observation and evaluation of these changes occurring in urban areas are crucial for making balanced and sustainable urban development. Today, through the use of remote sensing and information technologies, the assessment process of data is accelerating and the productivity is increasing. In recent years, night-time images have been often used in the studies that determine the urban areas. The fact that these images can be accessed quickly and their assessment process is fast increases the interest in the night images.

DOI: 10.4018/978-1-5225-2255-3.ch681

The method was used to detect a threshold value for Chicago, Miami and Sacramento states in the USA. Maps of urban areas were created from night-time images in accord with this threshold value (Imhoff et al., 1997).

It has been showed that a single threshold value in night-time images has been more appropriate to determine the urban areas for different metropolitan regions. Therefore, Henderson et al. have indicated that the threshold value of the data in night-time images should be determined separately for each year for which a temporal analysis needs to be carried out for urban growth detection (Henderson et al., 2003).

As there is very little fluctuation in light intensity in Italy's Sicilian city at night, Elvidg et al. have implemented a quadratic regression model to inter-calibrate among years by using the data of the city as the reference data. The purpose of using a single city for calibration in night-time images is to correct the changes according to the years in the satellite and detector sensors (Elvidg et al., 2009).

By examining the global economic and demographic differences of night-time images, Levin and Duke conducted a study that could be used as an indication of the demographic and socio-economic characteristics of the residential area at a local scale. In the study, the population data of the settlements Israel and West Bank (Arab and Jewish) were compared. It has been stated that the economic and geopolitical differences between Israel and the West Bank lead to pattern differences in night-time images (Levin & Duke, 2012).

Liu et al. carried out a study to uncover the relationship between making timely and right decisions about the dynamics of urban expansion in China between 1998-2002, urban growth, and the ecosystems and to optimize the ways of land use (Liu et al., 2012).

The study aiming to identify the variations of urban areas in major metropolitan areas in China between the years 2000-2010 consists of three steps; an average threshold for the reference year is determined in the first step, invariant features

(Pseudo Invariant Features) on the urbanization process are determined and then are normalized with respect to DMSP-OLS data PIF value. Linear regression model was applied in the normalization process. Furthermore an optimal threshold for urban area detection for each year has been designated with respect to reference threshold value and urban areas have been identified based on this (Wei et al., 2014).

MAIN FOCUS OF THE ARTICLE

The aim of this study is to obtain the urban sizes of 81 cities in Turkey by utilizing satellite imagery for 2010. Another object of the study is to apply different image analysis methods in order to determine the method which gives the optimal result in obtaining urban size and to compare these methods with each other. In this study, it is planned to compare two different methods, including object-based and pixel-based.

Used Data: What Are Night-Time Images

Night-time images for 2010 have been used to determine urban areas in Turkey. The NGDC started to develop algorithm in 1994 for global cloudless yearly night lights products collected by U.S. Air Force Meteorological Satellite Program (Defense Meteorological Satellite Program, DMSP) Operational Linescan System (Operational Linescan System, OLS). Temporal series of products are available at <http://ngdc.noaa.gov/eog/dmsp/downloadv4composites.html> and night-time images for the study area have been retrieved free of charge from this address.

By analyzing the location information, frequency and light image in temporal series of images, four kinds of main light sources in the world: settlements, fires, gas flares and fishing boats can be distinguished. Each pixel has 30x30 arc-second (or 0.86 km² at the equator) resolution and the images cover the area between +180 and

-180 latitudes and between -65 and +75 longitudes. Night-time images have been created as a composite presentation of two satellite images taken in cloudless nights. Each composite set has been labeled with satellite and year information.

These images used in the study contain data from fixed sources of light such as cities and towns. Moreover, background noise detection studies were carried out and these values were replaced with value of zero, and thus the image has been purged of these values.

Methods Used to Determine Urban Areas

Different types of features in digital images constitute combinations with different numerical values depending on the natural spectral reflectance and spreading properties. Earthly objects with the same spectral properties can be grouped benefiting from these differences. Assigning each pixel in the satellite images to the clusters corresponding on the earth with respect to the spectral properties and reflection values can be described as image classification. It is possible to divide the classification process into two main groups, namely pixel-based classification and object-based classification.

While determining the urban size from night-time images, two different image analysis methods, object-based and pixel-based, were used. Object-based image analysis method involves image segmentation and pixel-based classification method involves natural breaks and Otsu method. By comparing the results obtained through these three methods, the method that gives the most accurate urban area size has been determined.

Image segmentation can be described as dividing an image into meaningful regions each of which has different features in them. For example, there may be similar radiances in the image and these radiances can represent the objects in different regions of the relevant image. Pixels with similar reflectance properties during the segmentation stage are grouped and thus instead of working with millions of pixels, segments are formed by combining pixels with the common characteristics and at this stage the lowest heterogeneity level among segments will have been reduced. Depending on the importance of homogeneity or heterogeneity, users at this stage generate segmentation layers at various scale factors using spectral layers (Benz, et al, 2004). In addition, it is simplified to obtain many features during the classification using

Figure 1. Turkey night view of 2010

Figure 2. Application flowchart

features such as texture, length and area as well as the reflection features of resulting segments.

In this study, an image was divided into classes according to the edge detection (Edge Detection) method, an image segmentation method. In the edge detection method, the edge, lighting or surface reflections in an image correspond to significant changes occurring in the physical appearance of the image and this change shows itself as brightness, color and texture. In this study, in terms of edge detection, by looking at the changes in image brightness, the regions in which there are sudden changes in the gray levels of an image are called an edge (Aydin, 2014).

Maps obtained in the pixel-based image classification methods are produced so that the area of earth that image pixels correspond belongs to only one category. Classification algorithms produce a certain similarity function for assigning a value of any category to a pixel. In pixel-based

classification, an unknown pixel is assigned to the class label in which this pixel has the largest similarity value. The results of such a classification are univocal (Sunar et al., 2011).

In the study, image analysis method used as pixel-based contains two different applications, including the Otsu Method and Natural Breaks Method.

Otsu code method is a threshold setting method that allows determining the optimal threshold value of an image at a gray level that can be used while it is reduced to two groups. Otsu method is a threshold detection method that can be applied on gray level images. While this method is performed, it is assumed that the image consists of two color classes, including the background and the foreground. Then, in-class variance of these two color classes for all threshold values is calculated. The threshold value that enables this value to be the smallest is the optimum threshold

value. While in-class variance value is at minimum level, inter-class variance value becomes at maximum value. The method works on gray level images and only examines how often colors are on the image. So, the color histogram of the image is calculated firstly, and all operations are performed on the histogram array (Atasoy, 2015).

Natural Breaks method is a re-classification method. The working principle of this method is based on Jenks natural breaks algorithm. Jenks natural breaks algorithm is a classification procedure designed to determine the best way to organize the data in different classes. How many classes will be obtained in this method is described

and then pixel range values are obtained based on Jenks natural breaks.

SOLUTIONS AND RECOMMENDATIONS

Results Comparison of Images: Methods

By determining the urban areas according to the three methods, the urban area ratio of each province based on the total urban area across the country is presented as a percentage in Table 1.

Table 1. Percentage value of urban areas obtained by three methods in total urban area

Correlation analysis method was used while comparing each method to each other. In probability theory and statistics, correlation indicates the direction and strength of the linear relationship between two random variables. The method used to determine the degree of the relationship between two variables or the correlation is called the correlation analysis. The correlation coefficient r takes values between $-1 \leq r \leq +1$. $r = -1$ means complete negative correlation, $r = +1$ means complete positive linear relationship, and $r = 0$ indicates that there is no relationship between the two variables. The positive relationship indicates a tendency of increase in the values of Y variable in case of an increase in the values of X variable, or tendency of decrease in the values of Y variable in case of an decrease in the values of X variable. Negative correlation (negative relationship) means that if there is an increase in

the value of one variable, there will be a decrease in the values of other variables. The correlation coefficient of “0” shows that there is not a linear relationship between variables.

When Table 2 is examined, it could be seen that correlations of the three methods with each other is high; and there appears to be a very high positive linear relationship especially when the correlation coefficient between Otsu method and

Table 2. Correlation coefficient matrix between urban areas obtained by three methods

	Image Segmentation	Natural Break	Otsu
Image Segmentation	1.00	0.981	0.982

2	İZMİR	7.65	ANKARA	8.59	ANKARA	8.78
3	ANKARA	7.15	İZMİR	6.86	İZMİR	7.14
4	ANTALYA	4.75	KOCAELİ	4.71	KOCAELİ	4.55
78	GÜMÜŞHANE	0.16	ARTVİN	0.19	TUNCELİ	0.20
79	ŞIRNAK	0.11	GÜMÜŞHANE	0.19	ARTVİN	0.19
80	AMASYA	0.10	ŞIRNAK	0.15	ŞIRNAK	0.16
81	BARTIN	0.10	ARDAHAN	0.13	ARDAHAN	0.13

Natural Break method is examined. This high positive correlation between the two methods could also be understood when distribution of urban areas as percentage in Table 1 is analyzed. The distribution of urban areas give values close to each other according to both methods and the results obtained indicate a high proportion of overlap.

According to the three methods analyzed in Table 3, the cities with the largest and smallest urban areas have been identified. According to the results obtained from Natural Break and Otsu method, the first four provinces with the largest urban areas are respectively Istanbul, Ankara, Izmir and Kocaeli. The ranking of cities with the smallest urban areas are largely overlapping. According to these two methods, urban area values can also be seen to be close to each other. Image segmentation method differs a little in the other two methods.

Spatial autocorrelation relationship of the urban areas obtained from three methods has been assessed according to Moran I method. The relationship of the concept of spatial autocorrelation with geography was first expressed by Tobler (1970) in his words “Everything is related to everything else, but near things are more related than distant things.” It could also be describes as a positive or negative evaluation process of the spatial properties of the object depending on the distance. Spatial autocorrelation is expressed in three different ways (O’Sullivan & Unwin, 2002).

A positive correlation indicates that objects exhibiting similar properties cluster together. Negative correlation indicates that objects not exhibiting similar properties cluster together. Zero correlation indicates that there is no clustering between objects depending on spatial effects.

Considering Moran I values ranging from -1 to +1, it could be seen that there is a positive clustering in each method (Table 4). However, when the significance level 0.05 is taken into account, z value must be lower than -1.96 or higher than +1.96, therefore, the results obtained according to any method show a statistical significance.

This means that there is a positive spatial autocorrelation in the distribution of urban areas, namely it shows that large urban areas cluster together and small urban areas cluster together.

After the urban areas obtained through three methods, urban propagation map has been created. Urban propagation maps of three largest cities have been illustrated in Figures 3, 4, and 5 so that

Table 4. Moran I spatial autocorrelation statistical values

	Image Segmentation	Natural Break	Otsu
Moran’s Index	0.135	0.135	0.137
z-score	1.981	2.095	2.089
p-value	0.047	0.036	0.036

urban propagation map could be better understood and methods could be compared visually better.

FUTURE RESEARCH DIRECTIONS

In this study, urban areas were identified by classifying night images obtained by remote sensing methods according to pixel and object based classification method. At the same time, the methods used in the classification have been compared to each other statistically. Using higher resolution night scenes in future implementations of the study will contribute to the higher accuracy of urban areas. Moreover, this will give more precise results in Moran I values and the correlation used in the comparison of the classification methods.

CONCLUSION

In this study in which urban areas have been determined from night-time images by using pixel-based and object-based classification methods and these methods have been compared, the advantages and disadvantages tested have been discussed.

Identifying the threshold pixel value that divides the pixel-based image classification into two classes is the most important factor affecting the accuracy of the classification process. To determine the threshold value, in-class and inter-class variance values which are statistical parameters have been calculated. In addition, the appropriate threshold value has been determined by utilizing the histogram.

The basic principle of pixel-based Natural Break and Otsu methods used in our study is to determine a threshold value according to the distribution of the image pixels and to divide the image into two different classes with respect to this threshold value. Therefore, when examining the results obtained, it could be seen that the urban

area values obtained from both methods were very close together. The most important indicator of this is that the coefficient of correlation between the results of both methods is $r = 0.999$.

Working with occurring segments instead of pixels provide more information on the implications for thematic classes, but this raises the question of how information will be used effectively (Mallinis et al, 2008). In the object-based classification, classes of the working area can be easily created in the segmentation parameters identification level, namely in the segmentation process of the image. Through this approach, segments of pixels that have similar reflectance values are obtained for each class. The identification step of the pixel threshold value in the Pixel-based classification process is determined by the segmentation step of the object-based classification process. Although this case reveals a more accurate classification process and results, it causes the decision limits to be transitive.

The results obtained in the image segmentation method are shown to differ slightly from the other two methods. The reason of this is that the image after the segmentation process does not divide into two classes as in the pixel-based methods and the limits become transitive. Therefore, it requires user intervention in the creation of the precise boundaries of the urban areas. Despite this difference, the fact that correlation coefficients between the results of the image segmentation method and pixel-based methods are $r=0.981$ with Natural Break and $r=0.982$ with Otsu indicates that resulting values are highly correlated and alike.

In the results obtained from the Moran I spatial autocorrelation analysis of the investigated methods, urban areas have been found to spread spatially correlated. In this sense, it is concluded that major urban areas cluster around major urban areas, and small urban areas cluster around small urban areas.

KEY TERMS AND DEFINITIONS

Correlation: In statistics, dependence is any statistical relationship between two random variables or two sets of data. Correlation refers to any of a broad class of statistical relationships involving dependence, though in common usage it most often refers to the extent to which two variables have a linear relationship with each other.

Histogram: A graph showing the distribution of values in a set of data. Individual values are displayed along a horizontal axis, and the frequency of their occurrence is displayed along a vertical axis.

Moran’s I: In statistics, Moran’s I is a measure of spatial autocorrelation developed by Patrick Alfred Pierce Moran. Spatial autocorrelation is characterized by a correlation in a signal among nearby locations in space. Spatial autocorrelation is more complex than one-dimensional autocorrelation because spatial correlation is multi-dimensional and multi-directional.

Night-Time Images: Time series data of DMSP/OLS stable night-time light imagery span-

ning years 1992–2012 were derived from NOAA's National Geophysical Data Center. These image products provide gridded cell based annual cloud-free composited stable night-time lights with a digital number (DN) ranged from 0 to 63.

Object-Based Classification: Object-based image analysis, a technique used to analyze digital imagery, was developed relatively recently compared to traditional pixel-based image analysis. While pixel-based image analysis is based on the information in each pixel, object-based image analysis is based on information from a set of similar pixels called objects or image objects.

Pixel-Based Classification: The traditional pixel-based classification process automati-

cally categorizes all the pixels of an image into the thematic classes utilizing only the spectral information (relative reflectance) of each pixel in the image. The spectral information used by each pixel is also termed as a spectral signature, which is estimated by the relative reflectance in different wavelength bands.

Remote Sensing: Remote sensing is the acquisition of information about an object or phenomenon without making physical contact with the object and thus in contrast to on site observation.

Urban Area: An urban area is a location characterized by high human population density and many built environment features in comparison to the areas surrounding it.

Need for Rethinking Modern Urban Planning Strategies Through Integration of ICTs

Rounaq Basu

Indian Institute of Technology Bombay, India

Arnab Jana

Indian Institute of Technology Bombay, India

INTRODUCTION

Urban planners work towards achieving the three goals of environmental protection, economic development and social equity with the major focus being sustainable development (Campbell, 1996). Many practitioners feel that traditional urban practices have served their purpose, and it is time to search for a new approach which encourages openness and participation. However, conventional measures to enroll people in participatory planning activities have been found to be limited in both scope and reach. These findings coupled with recent advances in innovative technologies have led to opportunities to re-think the status quo in urban planning.

Information and Communications Technologies (ICT) have always been essential for new application opportunities. Recent progresses have paved the way for innovative communication services, and interactive models and tools for collaborative activities. Infrastructure can be made to dynamically and adaptively connect and collaborate in each other, thereby turning urban environments active and our cities into socio-technical organisms. Web 2.0, as suggested by O'Reilly (2007), has transformed the Web by turning it into a participatory platform where users can simultaneously consume (download) and share (upload) content. Web 2.0 techniques are linking users and data providers, thereby removing the barriers in direct communication that existed ear-

lier (Hudson-Smith & Crooks, 2008). Embedding these technologies into existing institutionalized processes still requires significant effort despite the collaborative and user-friendly nature of Web 2.0 services and applications.

ICT tools have the potential to radically impact modern urban planning strategies, thereby leading us into a new age of urban renaissance where we witness smart, digital, information and connected cities come to life. The applications of these tools vary widely, from a simple e-commerce service to complex data collection for decision making. These pervasive technologies have the power to impact dialogues between city managers and citizens, drive a shift to e-government services such as mobile health units and online payment solutions, and transform urban mobility through cloud communication and storage. The authors argue that there is potential for development of a new urban planning approach in which emphasis is given on active public participation through the use of Web 2.0 technologies. Thus, the role of urban planners needs to be redefined accordingly. Planners would benefit from integrating their current practices with modern ICT inventions to obtain socially inclusive long-term solutions. This chapter focuses on three of the most widely used ICT tools which have the potential for creating the highest impact in the field of urban planning: (1) Crowdsourcing, (2) Geographic Information Systems (GIS), and (3) Database Management Systems (DBMS).

DOI: 10.4018/978-1-5225-2255-3.ch682

The remainder of the article is organized as follows. The next section provides a detailed discussion about how crowdsourcing can be incorporated in the urban planning process. The associated challenges and benefits of its implementation have also been listed. Applications of a well-developed and vastly used tool in urban planning (GIS) are enumerated in Section 3, along with future research directions for further innovation. New ICTs have enabled us to collect and process large amounts of data. The importance of these tools (e.g. a DBMS or a web-based survey) is highlighted in Section 4. An application developed by the authors is also introduced in this section. Concluding remarks and future research directions are proposed in the final section.

BACKGROUND

Crowdsourcing is a relatively new concept that incorporates a variety of services and activities. It can be characterized by any category of collaborative activity over the internet (Estellés-Arolas & González-Ladrón-de-Guevara, 2012). Crowdsourcing involves mechanisms that aim to leverage the collective intelligence of users for a productive outcome (Brabham, 2009). Jeffrey Howe coined the term ‘crowdsourcing’ in an

issue of *Wired Magazine* (Howe, 2006). Simply put, crowdsourcing harnesses the joint creativity of the public by creating an open call for proposals through Web 2.0 technologies in the hope of innovative and more robust solutions (Seltzer & Mahmoudi, 2013).

A classic example of crowdsourcing is Wikipedia due to its strong collaborative nature. Using the generalized crowdsourcing model shown in Figure 1, let us further analyze the Wikipedia example. The organization (Wikipedia.org) floats a topic and asks users to provide details about that topic (the problem). Due to its open-source nature where all users can freely edit the article, information is obtained from a variety of sources (individuals, groups and experts). Once all users are satisfied with the content on that topic (solution), Wikipedia finalizes that article and publishes it as a page (implementation). The entire world (not just those who contributed) can now benefit from the knowledge in that article. This is a continuous process, as more users can update or edit the information with progress of time, leading to continuous quality monitoring and improvement.

The crowdsourcing model asserts that online communities have ‘collective intelligence’ (Pierre, 1997) and ‘crowd wisdom’ (Surowiecki, 2004). It is quite intuitive that cognitively diverse communities would provide perspectives that a field

Figure 1. Generalized crowdsourcing model

expert might easily overlook. This was concretely proven by Van Herzele (2004) in the context of urban planning. Citizen participation and open innovation are essential tools for urban planners looking for fresh insights into their projects. It is quite evident that non-expert knowledge emerging from future beneficiaries of policies is indispensable to governance. However, urban planners need to give adequate thought to public involvement given the many inherent difficulties in the process. Brabham (2012) has found the crowdsourcing model to be appropriate for facilitating citizen participation in public planning projects. The crowdsourcing model has also proved to be useful in myriad urban planning applications such as:

- Citizen participation in public planning projects (Brabham, 2009).
- Collecting and sharing geocoded data (Hudson-Smith, Batty, Crooks, & Milton, 2009).
- Collecting pollution data using smart-phones (M. Stevens & D'Hondt, 2010).
- Environmental and public health surveillance as well as disaster informatics (Kamel Boulos et al., 2011).
- Identifying street accessibility problems (Hara, Le, & Froehlich, 2013).
- Calculating urban air temperatures from smartphone batteries (Overeem et al., 2013).
- Determining urban form and function (Crooks et al., 2015).
- Mapping urban emotion information for evaluation of ongoing planning processes (Resch, Summa, Sagl, Zeile, & Exner, 2015).

Extensive and systematic reviews of the literature focusing on crowdsourcing and related concepts have been attempted by Mandarano, Meenar, and Steins (2010) and Zhao and Zhu (2014). It has been concluded that this field of research is still emerging rather than established. Evans-Cowley (2010) too has written that the impact of such

technologies on individuals, communities and cities is yet to reach its full potential.

U

Challenges

In aiming to obtain solutions from the masses, crowdsourcing opens itself up to face several challenges in the path to successful implementation of the process. The authors provide a summary of the major issues plaguing the use of crowdsourcing as a tool for urban planning. The reader is invited to refer to Howe (2009), Evans-Cowley (2011), and Pedersen et al. (2013) for further details.

Challenges in System Governance

- **Selection of the Right Model:** Multiple forms of crowdsourcing exist and it is important that the form is selected according to the objective.
- **Selection of the Right Crowd:** Attracting and sustaining the crowd is essential for multiple iterations, which leads to a robust solution.
- **Definition of the Problem Statement:** The problem statement should be well-defined and simplified, along with decomposition and distribution of different steps for a more efficient process.
- **Providing the Right Incentives:** Fair incentives help in attraction and retention of participatory populace. It was found that “each new prize should have approximately twice higher marginal utility than the prize immediately above it” (Archak & Sundararajan, 2009).
- **Selection of the Best Solution:** Individual ideas might be the best solution for each individual sub-task. Therefore, a mechanism should be in place for identifying sub-solutions which can be integrated together to obtain the most optimal solution. It is important to remember that such open calls lead to a veritable flood of responses, most of which might not be related or useful to the problem.

Challenges in Implementation

- **Bridging the Digital Divide:** Digital seclusion, i.e. inability to access the online world, remains a harsh reality in most developing countries.
- **Need for State-of-the-Art Infrastructure:** A sound technical support system is indispensable for maximum participation and user retention.
- **Cost:** Crowdsourcing requires time, money and constant monitoring.
- **Providing User Feedback:** Users need constant feedback about how the entire process is functioning and how their suggestions are being used. Providing feedback might aid in encouraging people to participate multiple times, which is a challenge often mentioned in literature.

Benefits

Despite the challenges that exist in applying crowdsourcing to urban planning, there are several positives as well. The authors next discuss briefly about a few of the benefits that crowdsourcing has provided to the research and planning communities. The reader is invited to refer to Brabham (2009) and Janssen, Charalabidis, and Zuiderwijk (2012) for further details.

- **Network Democracy:** The social order is moving towards formation of organized networks that co-exist with (and are thereby enhanced by) digital technologies (Rossiter, 2006). Crowdsourcing activities enable the public to feel as if the solutions have been made by them, i.e. a home-grown or an organic solution, and promote community participation and involvement.
- **Collective Intelligence:** It is a “form of universally distributed intelligence, constantly enhanced, coordinated in real time, and resulting in the effective mobilization of skills” (Pierre, 1997). The Web provides

the perfect platform for harnessing this intellect for working towards a networked democratic process (Rossiter, 2006).

- **Crowd Wisdom:** Surowiecki (2004) finds that “under the right circumstances, groups are remarkably intelligent, and are often smarter than the smartest people in them”. Thus, it is more desirable to collect the aggregate solution, rather than the average one.
- **Political and Social Benefits:** These include greater transparency, democratic accountability, public engagement, innovative social services and improvement of citizen satisfaction and policy-making processes.
- **Operational and Technical Benefits:** These include optimization of administrative processes, access to external problem-solving capacity, fair decision-making, improvement of public policies, greater ease in accessing data, and sustainability of data.
- **Economic Benefits:** These include stimulation of innovation, economic growth, and availability of information for investors.

GIS: USED BUT NOT SPENT

Introduction

Finding community-driven solutions for local problems is enabled by crowdsourcing; however, spatial factors often come into play while analyzing urban planning issues. Franklin and Hane (1992) found that 80% of data contains geo-referenced information. Therefore, a spatial analysis tool is required for data processing and visualization of patterns and trends, which aids in fast and better identification of underlying problems in the study area. Developed in the late 1960s, GIS can serve both as a database and a toolbox for urban planning. Barriers for initial use by planning agencies include limited capabilities of the software, lack

of skilled manpower and the extremely high cost of hardware. With advancements in technology leading to major improvements in both software and hardware performance, the use of GIS has become quite vital for urban planning. Visualization of databases and spatial modeling are the main uses of GIS in urban planning (Yeh, 1999). It has been pointed out by Douven, Grothe, Nijkamp, and Scholten (1993) that a major weakness of GIS in this sector is their integration with urban planning models.

Webster (1993) argues that the usefulness of GIS as a tool for planning can be best assessed with reference to the nature of the required data inputs. The potential contribution of GIS in predictive and prescriptive analyses for urban planning is discussed by Webster (1994). GIS technology offers opportunities to improve the quality of planning decisions through its support of both formal and informal analysis. The use of GIS over online forums can enhance citizen participation in the planning process by providing a platform for effective dissemination of information related to urban planning. GIS can be used for a wide array of diverse applications, some of which are outlined in Figure 2.

A few applications of GIS for urban planning over the years have been enumerated below:

- Open space planning for allocation of public facilities (Yeh & Chow, 1996).
- Evaluating neighborhood pedestrian accessibility (Aultman-Hall, Roorda, & Baetz, 1997).
- Modeling sustainable urban development (Li & Yeh, 2000).
- Simulating realistic urban dynamics for evaluation of development alternatives (Yeh & Li, 2003).
- Modeling the pattern and extent of urban sprawl (Sudhira, Ramachandra, & Jagadish, 2004).
- Evaluating urban expansion and land use change (Xiao et al., 2006).
- Hedonic price modeling of the amenity value of urban green space (Kong, Yin, & Nakagoshi, 2007).
- Predictive modeling of urban growth (Stevens, Dragicevic, & Rothley, 2007).
- Analyzing spatial patterns in metropolitan areas (Henderson, 2008).
- Determination of urban green space accessibility (Comber, Brunsdon, & Green, 2008).
- Creating a framework for landfill siting in a fast-growing urban region (Chang, Parvathinathan, & Breeden, 2008).

Figure 2. Diverse applications of GIS

Challenges

Technological advances with regard to software and hardware do not solely define the use of GIS in urban planning. The authors discuss briefly about some of the major challenges in this area, with particular regard to developing countries. The reader is invited to refer to Yeh (1999) for additional details.

- **Organization:** Separate studies have shown that factors related to the organizational structure and available staff are far more important when compared to technology for effective applications of GIS (Campbell, 1994; Maguire, Campbell, & Masser, 1997). Successful implementation of GIS requires (a) a dedicated information management strategy, (b) committed participation in the implementation of ICTs, and (c) a high degree of organizational stability.
- **Data:** Geographical data is readily available in developed countries, albeit at an expensive rate sometimes. However, developing countries face acute difficulties in collecting substantial data. Major inhibiting factors include (a) lack of financial resources, (b) lack of trained personnel, and (c) unavailability of modern data processing resources. Quality of data is an associated critical issue since data in developing countries are generally collected by external non-governmental agencies, which leads to a dearth of measures for quality checks (Batty, 1993).

Future Research Directions

Techniques for collection and use of data for participatory planning have seen major improvements over the past decade. However, their effective incorporation into GIS remains a goal to strive for (Dennis, 2006). Since GIS has been extensively used by researchers and planners all

over the globe, little remains to be explored in the technical domain. Therefore, formation of a community-based qualitative GIS should serve as a possible line of inquiry in the future. The major obstacles to this goal include the lack of community involvement and the absence of participation of external stakeholders or investors. Issues of local government and social service delivery have yet to be successfully handled through GIS, despite its widespread use by urban planners and policy makers. Since data pertaining to most urban studies are found in the form of maps, it is critical that modern mapping services are developed with integration of Web 2.0 tools in order to augment the visualization capacity of GIS models (Elwood, 2006). Web-based public participation GIS (PPGIS) practices were found to a valuable approach for fostering community engagement and promoting direct communication among users and decision-makers (Bugs, Granell, Fonts, Huerta, & Painho, 2010). It is evident that advances in information technology need to be integrated with existing methods like GIS to build a robust planning framework. Such a framework would also assist in assessing the desirability and suitability of alternative development plans.

DBMS: A BIG LEASH FOR BIG DATA

Introduction

As discussed in the previous section, one of the major challenges associated with GIS is the large amount of data required. Traditional means of data acquisition in such activities (on-site and photograph-based surveys) have severe disadvantages such as high costs or low participation rates. Developing countries often have to look for cost-effective alternatives, sacrificing quality for cost in the process. It has been found that web-based surveys have a higher response rate as compared to paper-based surveys (Kaplowitz, Hadlock, & Levine, 2004). Therefore, collecting such data within short durations at minimum cost

has now become possible through development of web-based surveys coupled with the use of DBMS. Applications of such surveys range from assessing built environment and visual landscape to monitoring the environmental impacts of urban sprawls and newly built transit networks. Reips (2002) provides a detailed list of the advantages (time and cost savings) and disadvantages (misunderstanding the questionnaire) of conducting online surveys.

Availability of vast amounts of data on a national scale, colloquially known as Big Data, is productive for understanding urban growth. Big Data facilitates flows of information and mechanisms of better understanding of heterogeneous individuals. Concepts such as ‘*smart urbanism*’ and ‘*real-time cities*’ are based on applications of Big Data in urban planning. Kitchin (2014) pinpoints emerging concerns in this regard such as the politics of big urban data, and corporatization of city governance and technological lock-ins. Batty (2013) describes how the emphasis is shifting from short-term measures for city management to long-term strategic planning due to the burgeoning growth of Big Data. Our capabilities to harness and analyze this kind of Big Data will lead to capturing information about every time horizon over longer periods of time.

DBMS in Developing Countries: Example

Although these concepts are used quite extensively in developed countries, developing countries are yet to embrace them for use in academic and industrial activities. The authors present an online survey technique packed with a latent DBMS structure that has been developed for collecting Big Data corresponding to citizen sciences, with a special focus on transportation, activity-time use and health care behavior.

Named ‘*Data Repository for Urban Models & Systems*’ (abbreviated as DRUMS), it provides complete freedom to the user (the academic institution in this case) to modify or delete existing

surveys, and even add new ones without any further efforts for writing new code. Although there are services such as SurveyMonkey, Typeform and Google Forms available on the internet, there are constraints such as: (a) limited number of free questions, (b) limited type and design of questions, and (c) data anonymity issues. Therefore, DRUMS came into being as a home-grown data collection and storage service that is expected to be a worthy alternative to similar paid services. DRUMS is currently hosted at this link: <http://www.cuse.iitb.ac.in/drums/>. The major advantage of DRUMS is that it enables citizen participation in urban planning approaches (see Figure 3). By linking end users with system developers, different surveys can be designed, modified and hosted to collect data with different exploratory questions in mind. All the collected data is stored in the database which is accessible only by the system administrator. In an effort to enhance the quality and use of open data, end users are encouraged to contact the system administrator in order to gain access to the data collected from their designed surveys. Citizens can thus perform exploratory analyses about the current community status in order to identify problems and propose solutions, all without the mandatory need of technical expertise (which is provided by DRUMS free of cost).

The benefits that DRUMS provides over manual methods of surveying are as follows:

Surveyor Perspective

- Can design and host multiple surveys without writing code (using developer tools).
- Can use sets of pre-defined question types (Multiple-choice, Dropdown, Boolean, Text-Based, etc.).

Respondent Perspective

- Can switch back to previous sections without loss of data (choices get locked in).
- Can close the browser tab which has the survey and reopen it without loss of data.

Figure 3. Traditional DBMS systems vis-à-vis DRUMS

- No loss of data even if device is disconnected from network.
- Can fill in data for multiple modes without filling in individual's data multiple times.

System Perspective

- Extremely quick collection of large amounts of data (Single sample of Survey 1 takes 10 – 15 mins).
- Region-independent data collection (city, state, or even country level).
- Highly cost-effective (only server maintenance expenses).

Such methods of data collection pose several challenges, especially in developing countries like India. Despite its multiple benefits, DRUMS has a few drawbacks like all of the previously discussed ICT applications. They are as follows:

- **Failure to Capture Varied Socio-Economic Categories of Population:** The socio-economic heterogeneity of the population is the major obstacle contributing

to the inability of the survey to penetrate all segments of the population and thereby hindering collection of a statistically representative sample. Although DRUMS has been tested only in India, the authors expect this concern to remain valid for most developing countries.

- **Dependent on Infrastructure:** Online surveys are largely dependent on technological infrastructure. Potential respondents are unable to access the survey during server downtime (due to network or maintenance issues) leading to loss of such samples because most people do not return to fill the survey at a later stage.
- **Knowledge Seclusion:** Several segments of the society, especially the economically weaker sections and the low-income groups, lack understanding of ICT applications despite owning and operating smartphones.
- **Digital Seclusion:** There are other groups which do not have steady access to the internet and are thereby excluded from participating in such data collection activities.

FUTURE RESEARCH DIRECTIONS

Future work should focus on exploiting the benefits of ideas generated by multiple users. Better and more useful organization of the feedback for urban planning also needs to be explored. Besides, future research questions may center on trust and reputation issues. In conclusion, the authors argue that integration of urban policies, modern technologies and fundamental concepts of engineering will lead to discovery of new solutions to important age-old urban problems.

CONCLUSION

This chapter explored different aspects of ICTs with regard to their application in urban planning. The authors believe that a paradigm shift in urban planning may be required with modern advances enabling collection of vast amounts of high-resolution data, faster analysis, and formulation of more complex and robust models. Citizen participation and public involvement were quite difficult earlier, leading to urban planning policies being solely in the hands of the government or municipal organization. ICTs have entitled citizens to feel more involved by providing them opportunities to have a say in the planning process. Since the impacts will have to be borne by citizens, it is only fair that they be given a fair opportunity to shape these policies. The authors believe that integration of traditional planning methodologies with modern Web 2.0 tools will significantly strengthen civic participation and will eventually empower citizens.

These tools and technologies, however, are not as easy to implement as is proposed. While developed countries have an abundance of resources in these sectors, developing countries have yet to make a complete leap to information technology for data collection and management purposes. However, the reluctance in handling and using complex ICT systems is slowly fading, as there are numerous examples of self-designed systems currently in use.

KEY TERMS AND DEFINITIONS

Big Data: Vastly large data sets that cannot be analyzed through traditional data processing techniques are collectively known as Big Data. Organizations in possession of Big Data (majorly business organizations) are attempting to capture and analyze even more samples in order to make sound decisions based on human behavior.

Crowdsourcing: The technique of presenting a problem statement to the public and floating an open call for solution proposals is known as crowdsourcing. The major advantage it possesses is that it uses modern Web technologies and tools for circulating the problem and collecting responses.

DBMS: Database management systems (DBMS) serve as an interface between the database and users, helping to ensure that data is organized in an easily accessible and comprehensible structure.

GIS: A geographical information system (GIS) is a computer system that enables storage and display of different varieties of spatial data so that underlying trends and patterns can be identified through analysis.

ICT: Information and communications technologies (ICTs) include any software, middleware, hardware or system that enables the transfer of information in an electronic or digital form.

Urban Governance: It can be defined as the system of processes through which a city is managed on a short-term scale, and the long-term development agendas are formulated and realized.

Urban Planning: It is a techno-political process that deals with the development of land, environment and public welfare along with design of relevant infrastructure, such as transportation and communications, which form the urban environment.

U

Reconstructive Architectural and Urban Digital Modelling

Roberta Spallone

Politecnico di Torino, Italy

INTRODUCTION

The digital reconstruction of contemporary architectural and urban complexes which were demolished, transformed or have been only theatrically conceived, remaining ‘on paper’, is now a tool of considerable heuristic value, allowing to preserve, interpret and create new images of cultural heritages that no longer exist in their original shape or never reached a material construction.

This chapter reviews methods and techniques of digital reconstruction, through an overview of the international theoretical statements, and then the author explores the potentials of three-dimensional reconstruction and the prerogatives of animation in the interaction with three-dimensional data.

The examination of several international case studies, and also some experiences personally conducted highlights the different strategies used for the preservation of the memory of such heritage.

BACKGROUND

The theme of the digital reconstruction of architectural and urban complexes is currently the subject of interest for many scholars and a field of convergence of different disciplinary viewpoints ranging from history of architecture, urban studies and environmental psychology.

This chapter privileges the point of view that takes as the central moment of the reconstruction the creation of interpretative digital models of a series of knowledge assumed through interdisciplinary researches. The relationship between architectural and urban dimensions is thought

seamless: the architectural complex, object of study, must be related to the urban context in which it was designed or it spent a special time in its life or it could live today, and the reciprocal transformations must be carefully recorded. In this way the object itself takes on an urban meaning. There could be several aims of reconstruction that, in this research ambit, goes beyond the mere iconographic documentation, to provide scientifically plausible readings of the analysed phenomena.

Several reconstruction techniques are inspired by Pagnano, Docci and Albisinni’s theories and methodologies of graphical analysis, applied to the design drawing as well to realize buildings, thanks to which the drawing can be identified with the model of understanding (Pagnano, 1975; Docci, 2009; Albisinni, 2011).

The scholars, adopting this method, re-draw and, or, re-model the space and use the graphic model as scientists reproducing artificially a certain phenomenon in the laboratory.

Reconstructive 3D modeling allows reviving an architecture and its relationships with the context, whether it is partly, or totally, lost, or hidden in the body of a building heavily altered, or, finally, it is going to be irreversibly transformed.

Representation and communication concern the knowledge data and their interpretation, resulting from the documentation phases. The digital models are the most useful database for collecting and synthesizing these analyses.

The modeling is therefore a cognitive strategy in which the idea of similarity, in comparison with the reality, plays a decisive role, a strategy that is utilized in different ways depending on which kind of model it is going to carry out (Gaiani, 2004)

There are several stages in the 3D reconstruction of a built complex. These include the gathering of the source information, the interpretation of this information, the comparison with contemporaneous examples, the development of 2D blueprints and/or 3D geometric (or parametric) models of the building and its context, the texture mapping, the addition of lights and, finally, the rendering.

Transforming several drawings into a digital model is a process which changes one model into another and deserves some attention. It is, as a matter of fact, not a simple variation without alteration of contents, but, on the contrary, it modifies, from time to time, “the wealth of the model, its expressive potentiality. In fact, the transmutations of the models are moved by the interpretative intent of the scholar, and they converge, therefore, toward an abstract model... that we can identify in the project idea” (Migliari, 2004).

The creation of a 3D digital model offers, as a result, infinite possibilities of observation and survey: from the objective visualization of a cylindrical projection, orthographic or isometric, to that subjective of a conical projection, perspective (Spallone, 2007). The model thus becomes an essential tool to check and control the validity of reconstructive hypotheses and the congruence between the building elements.

Moreover 3D computer models allow more enhanced and controlled interaction between users and models; they are able to cover the whole range of possible models in a single system of representation (Maldonado, 2005).

Conceived as real maquettes, which live in a virtual space perfectly corresponding to the real one, so much to offer all the four dimensions, the models carried out by means of computer are then observed through a screen..., with capacities to vary the point of view in order to simulate the mobility and the transformability in the time and in the appearance. (Gaiani, 2004)

In the operational strategy that ascertains the models attributes, a central moment is the

definition of the ratio between representation/visualization scale and modeling details. Since all the models are simplifications and schematizations of the reality, there is always a difference between the real and the details that are included in the model.

Even a very detailed graphic reconstruction, of an architectural product, aimed at giving the viewer a stimulating image of reality, will always necessarily be the result of a synthesis... A synthesis always implies the exploitation of specific aspects to the detriment of others and consequently a data loss. (Galifi, Moretti, & Aoyagi, 2002)

The increasingly enhancements of digital technologies also in the ambit of renderings, in many reconstructions, appear in the ability to produce high-level photorealistic imagery: digital processed images seem to be photographs of a real object, represented as if it had just been built. In this case, photorealism become sometimes hyper-realism overcoming the limits of truth likeness.

It is the reason why the author prefers the conceptual 3D models to which materials like clay are applied to the opaque surfaces, and glass to the transparent ones, for simulating physical plastic models. This latter kind of render allows to appreciate the shape generation, the geometric relationships between the building and its context, the perception of the interior and exterior spaces. When the model becomes part of an animated sequence, only some stop-images could be rendered by soft realistic imagery.

In any case the author shares with Ogleby the idea that “what is lacking presently is both an ontology for visual literacy in the area of virtual heritage, and some method of adding to the viewer’s understanding through the supply of supporting information” (Ogleby, 2007).

The ability to access the fourth dimension, through the construction of a sequence of images, constitutes a specific prerogative of the digital representation, which goes beyond the static constraint imposed by the conventional

methods of representation (Garzino, Spallone & Lo Turco, 2011).

Manovich dates back the rise of the movie camera as a universal paradigm for interaction with data represented on three dimensions to the 1980s and 90s, when the interaction between users and virtual models through an interface began to use actions like zooms, tilts, pans and tracks (Manovich, 2001).

The production of movie and animation of 3D models has to focus on well-organized sequences relating to space, event and movement.

As Engeli noted, the creation of specific messages relating to space requires an in-depth knowledge of the characteristics intrinsic to the different possibilities and to the aspects that are wished to emphasize (Engeli, 1999).

The animation, as a tool of the digital reconstruction, highlights its potential in enabling the exploration and dynamic perception of objects, spaces and contexts that no longer exist, or never really existed, but also to represent thematic readings such as periodization, decompositions, building sequences that find the most effective means of communication in the fourth dimension.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

As said, currently, the digital reconstruction of contemporary architectural and urban complexes relates to the artefacts that have undergone demolition or transformation or never realized ones. They have in common the fact that they exist today as a proof on paper as if they were or could be.

In any case, sketches and drawings, sometimes accompanied by the plastic models, are the main source for the reconstruction of the project.

Regarding to the sources, in the case of the demolished buildings some illustrative materials can witness the different design hypothesis up to the detailed design and even consist of surveys carried out afterwards, usually enriched by a

photographic repertoire. In the case of unrealized projects the graphic documentation, generally patchy and fragmented, often does not reach the level of detailed drawings. However, several materials, that lend themselves to numerous different interpretative readings, have to be put in relation. In addition, the hypothesis of considering the inevitable missing data is a common need.

Regarding to the reconstruction strategies, in the case of demolished or transformed buildings, several solutions can be reconstructed with different models, or even the final draft, that often deviates from the actual realization; in the case of ideal designs, different hypotheses can be followed and the missing elements can be integrated by the comparison with other existing works. In both cases, the author believes that digital tools, methods and techniques of representation should be carefully selected and adapted to the characteristics identified through the interpretation of the project and that is intended to communicate.

Several scientific approaches adopted by international scholars with respect to the case studies outlined above are addressed in the subsequent discussion, not aspiring to an exhaustive treatment of the topic.

Kahn's unbuilt masterworks and uncompleted projects are the subject of numerous and different studies, involving also a research conducted by the author, supervisor of some bachelor candidates.

Larson, in a book containing the reconstruction of six Kahn's unrealized buildings (Larson, 2000), raises some important questions related to the role of digital modeling for the reconstruction of unrealized projects, which can be extended to objects of the present chapter. He observes that the incomplete evidence left by Kahn could be the score of a performance, where personal interpretation and addition of details are permitted and then discusses about the representation methods and rendering techniques to be used in the reconstructive process. In fact, the synthetic nature of the image could be established through conceptual, non-perspectival sections and isometrics, or impossible views like the section-perspective.

Ambiguous imagery could be created, as Kahn did in his design process, with grainy black-and-white photographs of models that highlight the essential elements and obscure the missing details. These considerations, focusing on the interpretative potential of conceptual modeling, seem to be contradicted by the figurative choices consisting of hyper-realistic images chasing perfection and sharpness of architectural photographs available in contemporary magazines.

Despite Larson's ability to create imperfections in materials, some patterns are visibly repeated and the atmosphere seems too thin. Also it lacks an overall vision of the design that makes understanding the relationship of the building with the environment and its internal functioning.

Dotto develops a study on Kahn's unrealized design of Hurva Synagogue, documented in three versions (Dotto, 2012).

He argues that the shape of absent architectures can be investigated and represented disclosing the partially hidden aspects in the design drawings, right through new drawings making more

accessible the works that would not otherwise be available for study and research.

The attempt to reconstruct the path of Kahn's project also trying to tidy up the chronological sequence of undated drawings, leads to plot a story that highlights the uncertainties of interpretation.

The construction of the virtual model has the advantage of allowing a check of the geometric, spatial and formal coherence of the available representations.

About the digital model display, Dotto raises the question of the use of drawing and modeling as tools of communication, different from the photograph, which triggers the processes of imagination and interpretation of spaces and forms. For this reason he promotes the use of orthographic projections, isometric cutaway, perspective sections, and graphic overlays. Similarly, surface treatments and lightings rather than pursuing photorealism and truth likeness should evoke the visible reality using the instruments of graphic abstraction.

Also a research conducted by the author relates some unrealized and incomplete Kahn's works.

Figure 1. Graphic analysis of the third design of Hurva Synagogue. Cut-away perspectives of the three versions of Hurva Synagogue design.

Source: Dotto, 2012

Among these, there is the unbuilt U.S. Consulate in Luanda (1959-'62) and the incompletely built design of the Salk Institute in San Diego, California (1959-'65), modelled respectively by the bachelor candidates Tancredi and Alberti, supervising by the author.

The design of the U.S. Consulate proposes the incorporation of unglazed, independent forms borrowed from the ruins of the ancient world, which Kahn saw during his stay in Rome, into a very modernist architecture.

In the building Kahn addresses the problems of climate by developing two design themes: the ruins wrapped around the buildings and the separated roofs for the sun and the rain.

Tancredi chose to display the model, mainly in parallel projections, with the aim to highlight the correspondence between the two buildings, the internal distribution, the structural system

and the performance of the vertical diaphragms (the ruins) and horizontal (the double roof) with respect to the climatic conditions. The roof plan of the whole building shows correspondence in size, alignment and roof perforations to the sun and the rain; cutaways and exploded isometrics show functional partitions and load-bearing supports; the setting of shadows shows the solar behaviour. The application of photorealistic materials and lighting to the perspective scenes in which there are also daily life elements offers possible foreseeing of the artefacts and spaces designed by Kahn.

The Salk Institute for Biological Studies, along the Pacific coasts, designed by Kahn included laboratories, the only that were built, the meeting house and houses for the fellows.

The theme of ruins as devices to control glare appears also here as three-dimensional, complete forms that define and enclose space. Indeed, fully

exterior and independent cylindrical ruins wrap around cubic inhabitable space, and cubic ruins wrap around cylindrical inhabited space.

Alberti aimed to represent Kahn's project in its context as if it were entirely built.

The relationship with an environment strongly characterized by the dry rocky slope overlooking the sea, the spatial articulation of the three architectural units and the careful choice of materials, are Kahn's design themes, which inform the choices of representing the model of the complex inserted in the environment as if it were a plastic model. The terrain has been shaped by extrusion of the contour lines giving the environment a degree of abstraction comparable to that of the artefacts. Even the colour attributed to all the natural elements through the application of a material that evokes the cork allows distinguishing them from the buildings clay rendered.

The final product of the representation is a 7 minutes video, which allows exploring dynamically the three units thanks to the fly and walk through. Only a few still images in photo-realistic rendering with fast fading effect can evoke a perceptual effect generated by materials and real lights.

Also the archival drawings of contemporary masters, currently the subject of renewed attention involving scholars in different disciplines and making use of the tools provided by digital world and convergence of its products, are object of a research line aimed to the digital reconstruction, conducted by the author.

In particular the research concerns several designs by Carlo Mollino, whose archive of drawings is preserved in the library of Architecture at the Politecnico di Torino, and characterizes a series of the master's theses, supervised with Sergio

Pace. The subjects until now studied are the Turin Horse-Racing Society Building, demolished in 1960, two ideal houses published respectively on the magazines *Domus* (1942) and *Stile* (1944), and the competition design for the Palazzo del Lavoro in Turin (1960), unrealized because it did not win.

The Horse-Racing, an early and acclaimed work by Mollino, had a short life (from 1937 to 1960). Its demolition was connected with the wider process of urban transformation, which involved the area along the west bank of the river Po, triggered by the celebration of the Unification centenary of Italy.

The digital reconstruction of the building has been realized by Canaj during her master thesis.

She also analyzed the relationships between the building and the context, less dense than the current, but strongly characterized by different buildings, reconstructed by means of the archival city maps and design drawings.

The Horse-Racing has been reconstructed in detail, once those archival drawings were identified to allow the most faithful reproduction of reality, after filling in the missing information and resolving ambiguities and inconsistencies of the documents. In this sense, the re-drawing of the project takes on the meaning of a true re-design that requires a deep understanding of the artefact and poetics of the architect.

The modeling phase has been carried out with the technique of 'blueprint', using CAD and 3D graphics software, arranging plans and elevations on orthogonal planes so as to foster the most appropriate control of the process.

The model has been lightened with sunlight while, about the materials, the opaque surfaces have been rendered using clay and the transparent ones with glass. In this way the model maintains the proper level of abstraction and avoids generating the sense of fake that characterizes the photorealistic reconstructions. The choice to represent the perspective views of the model in black and white goes to the same aim, allowing also a comparison with the vintage photographs taken under the guidance of the same Mollino.

Further processing, which aims to compare the digital model renderings with the original photomontages, and to search the same view points and solar illumination conditions, has been led to try a new photomontage of the model in the portrayed old context.

The Casa sulla collina (1943) and Casa sull'altura (1944) are two ideal houses designed by Mollino, digitally reconstructed by the master candidate Laudani.

The issue of the ideal houses animated the Italian architectural debate, during the period of the forced inactivity due to the II World War, so that several architectural magazines became promoters of the initiative to request and publish projects of the contemporary top architects on this subject.

In both case studies, the publication of drawings was accompanied by Mollino's writings to the editors, which described the concept, his reasons and widens the speech stating his position with respect to the debate.

Carlo Mollino was an architect who combined the research of architectural quality to a strong knowledge and experience of building (Pace, 2006), because he worked, from the beginning and for about twenty years, with his father Eugenio, an engineer particularly productive especially in Turin area.

The relationship between the drawing and the constructive reality emerges also in Mollino's designs programmatically intended to remain on paper, of which also the technological details in large scale were graphically defined, the interior furnishings were designed as an integral part of the architecture and, even, the static schemes of some structural elements were traced.

The particularity of Mollino's *modus operandi*, which was expressed through hundreds of drawings for each project, led the author to propose the student to use a parametric three-dimensional modeller like BIM, aimed to the three-dimensional reconstruction, in order to assess the three-dimensional consistency of the two-dimensional archival drawings, checking possible variants and obtaining sections from the

Figure 4. Two-dimensional re-drawing of Horse-Racing Society, plan and elevations. Original scale 1:200. Photo-montage between rendered model of Horse-Racing Society and original photograph. 3D model, provided with the graphic standards of the architectural technical drawing and settable at different scales, selected also in order to compare them to the sources.

The reconstruction was completed by a video and a plastic model digitally fabricated: a demountable material model, made with a small 3D printer which extrudes fibres of polylactic acid.

Through these operations, for the first time the design has been freed from the two-dimensional support through the transformation in three-dimensional digital model (always accessible through the two-dimensional space of the screen), achieves the fourth dimension by the production of the video that allows to visit, offering new views, and finally truth imbued in a three-dimensional material object.

In addition, through the examination of some drawings by Mollino, who placed the Casa in collina in relationship to the centre of Turin, its location could be hypothesized, imagined by the architect on Monte dei Cappuccini, near the

XVII century church. The photo-montage of the 3D model in the current environment highlights a shocking antagonistic relationship between the house and the church for the conquest of the hill-top.

Other subjects of reconstructive modeling are some minor architectures realized in Italy during the Thirties on charge of the Fascist Party, today demolished or deliberately lost due to their symbolic means.

Francesco Maggio conducted researches on some 'forgotten' buildings of the fascist period.

In the case studies of the Fascist House (1929) by Enrico Del Debbio and the Post Office (1936) by Angiolo Mazzoni, both located in a square of Agrigento, the author compared the 3D model drawn out by the design drawings and the survey of the existent building, and underlined the relationships between the two buildings and the transformations of urban tissue (Maggio, 2008).

On the same subjects the research experience, carried out by the author and Bruno jr. with some

bachelor candidate, concerns the digital reconstruction for the preservation of the architectural heritage memory (Spallone, Bruno jr., 2013).

The reconstructive operations started with the analysis of the archive documents, the search of old photographs, postcards and city maps, aimed to insert the building in the context, and a survey on the building materials utilized at that time. After this first step of data collection, the digital reconstruction of the building and the urban tissue began. The interaction among different disciplines, such as history of architecture, representation and also material technology guaranteed the experiment a higher scientific level.

One of the case studies analyzed, the Casa del Marinaretto, built in the Thirties and demolished without any consideration in the early sixties, shows such original and interesting design solu-

tions, that the preservation of its authentic memory and its valorisation seem justified.

The Casa del Marinaretto was designed by Costantino Costantini in Turin, close to the river Po, looking like a big 'urban anchored ship', constituting a high quality building with international inspiration. The work moves after the rigorous analysis of the archival original drawings and proposes the reconstruction of the building according to its original version as it was drawn by the architect for the first time, and so in a different manner respect to the built result. This process guarantees also the 3D perception, the authenticity of the materials and of the location into the urban context, using digital static and dynamic rendering systems. The 3D model of Costantini's project, inserted into the urban and natural context of our days, to simulate the perceptive effects that

Source: From the bachelor's thesis by Francesco Carota. Supervisor: prof. Roberta Spallone, advisor: prof. Andrea Bruno jr.

the building could express today as if it was still standing, was realized by Carota.

The model, realized using 3D computer graphics and animations programs, was the basis for the production of a video-clip that dynamically explored the relationship between the actual image of Turin and the Casa del Marinaretto as if it still existed.

Again in Turin, Costantini built the Fascist house in via Guastalla aimed to accommodate the youth organizations and at the same time to ensure a gym to the adjacent school.

This building, now in a poor state of preservation, exemplifies the architect's ability to adopt the rationalist language, working on the sharpness of the shape, the absence of ornamentation, the use of materials and technical choices consistent with modern era, such as the use of glass bricks

and roofing flat. The digital model of this building, reconstructive of the original design, today heavily altered, shows the main elements which characterize a building of great balance and lightness, free from rhetoric of the regime or by self-complacency. It was realized by Businaro using BIM technologies with the aim of creating a database useful for managing the predictable actions of functional requalification and energy efficiency improvements.

SOLUTIONS AND RECOMMENDATIONS

The originality of the approach, here developed and proposed, is the thesis that the tools, methods and techniques of representation (graphical analysis, bi

Figure 8. Digital reconstruction of the original configuration of Fascist House in via Guastalla. Two-dimensional drawings obtained by 3D model and cut-away isometric. and three-dimensional modeling, animation, prototyping etc.) should be chosen with care, case by case, in order to properly interpret the knowledge data and generate interpretative readings, using as sources and ideas for research not only the archive drawings and any surviving vestiges, but also autographs writings and significant analyses of architectural critics.

FUTURE RESEARCH DIRECTIONS

The digital reconstructions are emerging as important tools for understanding, interpreting and sharing the cultural heritages. The wide and continually increasing availability of tools offered by the digital world makes thinking, on the one hand, the application of the latest game engines for interactive exploration of the reconstructed complex, on the other the use of augmented reality to enrich the informative content of the archival heritage.

CONCLUSION

This chapter develops some considerations about the issues raised by the digital reconstruction of contemporary architectures and urban context no longer existing in their original configurations.

Through the overview of the international theoretical positions, different scholars' critical approaches emerge.

Generally archival drawings are patchy and fragmented and refer to different ideation moments and paths of inspiration that lend themselves to numerous and different interpretative readings. The other sources of knowledge of the artefact, even when it was built and transformed or demolished, have similar characters of variability and fragmentation. Moreover a careful analysis of the author's poetics and significance of his work is necessary. Digital methods and techniques of representation, ranging from 3D modeling, video producing, digital fabrication and other future

application of digital technologies, should be carefully selected and adapted to the characteristics identified through the interpretation of the project. The path of knowledge, which should be as wide and deepened as possible, and the possible interpretations that follow, will suggest the reconstruction strategies of the complex.

KEY TERMS AND DEFINITIONS

3D Modeling: In 3D computer graphics, 3D modeling is the process of developing a mathematical representation of any three-dimensional surface of object via specialized software.

Animation: Animation is the process of creating a continuous motion and shape. In the architectural representations, animation can be the creation of a path inside and outside of buildings, or the putting in motion of static elements.

BIM Modeling: Building Information Modeling (BIM) is a digital representation of physical and functional characteristics of a facility. BIM involves representing a design as combinations of objects that carry their geometry, relations and attributes.

Blueprint Technique: It is a modeling technique which consists of having plans and elevations on orthogonal planes so as to ensure the selection of modeling operations and foster the most appropriate control during the process of creating three-dimensional digital model.

Digital Reconstruction: It is the process of reconstruction of a disappeared building or modified over time, by means of 3D computer graphics programs, typically starting from archival documents and surveys.

Regional Development and Air Freight Service Needs for Regional Communities

INTRODUCTION

This article is intended to assist in documenting the needs of regional communities with regards to airfreight services. In doing so, the article first considers the importance of air service access to small and regional communities with particular emphasis on those economies bolstered by agriculture and the production of high-value, low weight, perishable products. The article then explores the airfreight challenges facing regional communities and discusses the needs for: integration; infrastructure; and service reliability. The article provides an overview of potential solutions to assist in meeting these needs, including: improving the flow of information and communication; and applying electronic commerce strategies.

BACKGROUND

Over the past two decades, the air cargo industry has grown dramatically (Yuan, Low, & Ching Tang, 2010). Although world air cargo traffic stagnated from mid-2011 to 2013 (Boeing, 2014), growth returned in 2014 accounting for approximately 35% of global merchandise trade by value (International Air Transport Association, 2015). The dramatic growth in the global airfreight sector may be explained by three observations.

Firstly, the dramatic growth in airfreight can be explained by an apparent industry trend towards the production of high value, lightweight goods (Ari-Pekka & Hintsa, 2009). This includes the new economy associated with the transport of fresh, perishable, high value produce (Sim, Barry, Clift, & Cowell, 2007). Statistics support this emerging economy highlighting that the transport of perishable food accounts for 14% by volume of total global airfreight (Bridger, 2008). Secondly, producers and shippers are realizing that the higher costs associated with airfreight can potentially be offset by the costs savings associated with storage, and packaging when using other freight modes (Yuen et. al., 2010). Finally, on a global scale, air service costs have experienced a reduction due to the entry of large numbers of wide body freighters to the logistics industry (Gardiner, Ison, & Humphreys, 2005). As such, the overall effect is that airfreight is becoming a commonplace business decision in the distribution systems of many companies (Murphy, Dalenberg, & Daley, 1989).

Increases in the perishable airfreight task are linked to the emergence of a social focus on the consumption of foods produced from regions known for 'clean' production processes. This new social focus has called for research, which investigates the food chain in an effort to understand rural development patterns (Renting, Marsden, & Banks, 2003). Thus, sea, road, rail and air

transport of freight in the food production cycle from the farm to the consumer's table has come under scrutiny (Saunders & Hayes, 2007). The scrutiny has been applied in the pursuit of clarity surrounding the cost of transport to the environment, society and communities.

Regional communities are the first step of the food production cycle. For many regional communities, access to airfreight networks means an opportunity to penetrate and participate in markets that cannot be equally serviced by other modes of transport. For perishable agri-producers, access to market requires access to appropriate freight services with the ability to transport products efficiently and effectively from the farm to the consumer plate. Thus, understanding the needs of regional communities with regards to airfreight access is an important factor in fostering sustainable economies for these communities (Kille, Bates, & Murray, 2013).

Although air cargo decisions are becoming the norm in the distribution systems of many companies (Murphy et al., 1989), there is little recognition of the needs of regional communities with regards to airfreight access. There is a plethora of literature and research into international and domestic air cargo utilizing the cargo space of wide body passenger jets or dedicated aircraft freighters. However, there is a shortage of literature on another critical part of the perishable cargo supply chain (i.e., regional aviation and the associated airfreight service needs of regional communities). Furthermore, much of the current literature and studies focus on the needs of shippers in an international setting and provide little to further our understanding of how decisions associated with airfreight fit contextually within a regional community and their economic development. The authors contend that information and technology lie at the core of airfreight service needs of regional communities.

For the purposes of this article, a small or regional community is taken to be one that maintains a 'rural airport' as defined by the United States Internal Revenue Service (IRS). The IRS defines

a 'rural airport' as any airport that has fewer than 100,000 commercial passengers departing from the airport during a calendar year, and at least one of the following is true: a) the airport is not located within 75 miles of another airport from which 100,000 or more commercial passengers departed during the preceding calendar year; or b) the airport is not connected by paved roads to another airport (United States Department of Transportation, 2016). Regional aviation includes the air transport operators serving these rural airports.

This article investigates the needs of regional communities with regard to airfreight services. The author reveals that information and technological challenges may be overcome by addressing the key airfreight network areas of concern including: (1) integration; (2) infrastructure; and (3) service reliability.

THE CHALLENGE: AIRFREIGHT SERVICE NEEDS FOR REGIONAL COMMUNITIES

A number of challenges for the regional air transport sector of the perishable food supply chain have emerged. This section explores the impact of: integration, infrastructure, and service reliability on the provision of services to regional communities.

The Need for Integration

Access to air transport services and feeder services is often limited for rural communities. For example, the scarcity of freight forwarding providers presents significant challenges for growers who are left uncertain about availability of potential logistics providers in the region. Rundle (1998) explains that the limitations imposed on agricultural exporters is rooted in the passenger demand and scheduling policies administered by domestic airlines. Hanaoka and Phoosanabhongs (2010) support this and assert that reliability becomes a

key concern for shippers when the cargo capacity of an aircraft is used to accommodate both passenger services (i.e., baggage) as well as freight cargo. When an airline encounters difficulties associated with weight and balance, it is not passengers or baggage that are offloaded but the freight cargo.

Dedicated airfreighter services, however, are not common for regional communities. As such, it is often the regular passenger air service (where available) that offers the only method of freight transport by air. Batt and Morooka (2003) argue that cost is not the only decision element for producers of high value perishable products. When planning the mode of freight transport to use, it is usual for shippers of these products to equally consider reliability, strength of network and shipping elements that ensure the quality of the produce at delivery. These elements of logistics decision-making must be addressed by regional airfreight suppliers with consideration to the importance of integration requirements in strengthening service delivery. The transport of high value produce via air offers an additional revenue stream for passenger airlines and Popescu, Keskinocak, Johnson, LaDue, and Kasilingam (2006) contend that airlines, thus, must ensure that cargo capacity is managed effectively. The application of an effective cargo capacity forecasting model (similar to the passenger overbooking model utilized by many passenger airlines), should be considered by air transport providers handling cargo in an effort to enhance the utilization of cargo capacity (Popescu et al., 2006). Proficiency in this area offers the potential for regional airlines (often with thin margins) to achieve business success.

Fundamental elements of the 'farm to table' movement include prompt, reliable and quality transport services. It is apparent that a variety of transport modes are required to transport freight produce from the farm gate. Accordingly, it is essential for air service providers to collaborate with other freight transport modes. The advantages of integration in the supply chains of the food industry are explored by Stank, Crum, and Arango (1999) who support the coordination in processes

(such as communication, information technology, partnering, and performance monitoring) between firms. Such integration will encourage broad improvements to critical logistics performance areas (Stank, Crum, & Arango, 1999). For regional airfreight providers, the most significant obstacle will be the sharing of crucial business process information and operations with providers of other freight transport modes.

Lillie and Sparks (1993) concur that shippers of high value perishable products value equally both cost and total freight service offering. More recently, however, speed-to-market delivery requirements, and the management of the supply chain have expanded demand for complementary intermodal transport services and infrastructure. For those rural communities supplying the 'farm to table' movement, integration is a significant issue and a facility to engage complete door-to-door services through a single platform is most coveted for such shippers (Tseng, Yue, & Taylor, 2005). The pragmatic application of the concept of integration will be a challenge for regional airfreight providers. Hence, integration in freight-forwarding will need to be forged by key regional stakeholders able to communicate with and appreciate the scope of freight services available at one time (Kille, Bates, Murray, 2014).

The Need for Infrastructure

Specific climates within specific geographic locations often form one of the key attributes for many niche agri-products. Although the uniqueness of the geographic location is frequently the basis for the product success, the locality can also become a hindrance with respect to the time and distance the product travels to processing centers. Financial incentives and government supported research is necessary to attract investment in this area. With access to quality information, investors and producers can make more appropriate long term decisions associated with the development of infrastructure, innovative growing technologies and sustainable growing practices (Kille, Bates,

& Murray, 2014). For example, Gardiner et al., (2005) assert that airports offering marketing assistance (such as the funding of research activities) increase their chances of attracting airlines and associated investment opportunities.

Effective airfreight services are highly dependent on factors including the geographic location (Gardiner et al., 2005) and relative infrastructure of the airport. A recent study examining international cargo gateways found that airports within close proximity of shippers generally have lower costs and lower delivery times which assists those airports to develop into regional air cargo hubs (Zhang, 2003). While the regional airfreight sector is challenged by competing modes of transport, realizing the importance of airport location can make airfreight options competitively more attractive. Freight by air is generally considered a greater expense when compared to road, rail or even sea transport. However, the reduced transport time (often associated with airfreight) lends to reduced time and costs associated with storage. Balancing costs in this way may project airfreight as a reasonable mode of transport for certain transport purposes.

Further infrastructure related challenges impacting on the regional airfreight sector includes customs clearance efficiency (Zhang & Zhang, 2002) and access to skilled and well informed freight forwarders (Gardiner et al., 2005). Government and council imposed environmental restrictions imposed on airports, (such as curfews on night operations), also challenge the operations and development of airports (Shaw, 1993). Kille, Bates and Murray (2014) propose that environmental limitations such as these can be overcome with community cooperation and engagement, which aims to balance environmental concerns (such as noise restrictions) with economic limitations.

Availability and access to tangential facilities is an additional infrastructure challenge facing regional airfreight operations concerned with the movement of high value perishable products. Kille, Bates, and Murray (2014) suggest that appropriate access to tangential facilities such as cold storage, may strengthen the overall service quality and

reliability of the entire freight transport service. Yuan et al. (2010) concur, contending that the enhancement of airport infrastructure to include cold storage facilities nurtures the opportunity to improve the overall performance of airfreight services.

The Need for Service Reliability

The term 'service reliability' in logistics is established in a compact body of literature (Gardiner et al., 2005; Yuan et al., 2010). Park, Choi, and Zhang (2009) explain that service reliability includes attributes of accuracy, punctuality, dependability, and safety.

The challenge of service reliability is unavoidably linked to the two challenges discussed previously, as adequate service integration and suitable infrastructure are key characteristics of 'service reliability'. It is the speed and reliability requirements of modern supply chain management processes that has supported the rapid development of airfreight and express air cargo services (Park et al., 2009).

A study conducted by Foster and Strasser (1990) explored fundamental factors defining the carrier/modal selection of shippers. The inquiry uncovered that the most dominant selection variable for shippers was 'schedule reliability'. The significance of cost and service variables, before and after the impact of government imposed deregulation policies, was considered by Murphy and Hall (1995). The research revealed that when considering choices of freight transport, shippers predominantly rank 'service' higher than 'cost'.

The elements of competition impacting on regional airfreight are similar to those challenges recorded in the international studies (i.e., locality, cost and frequency). Thus, comparative conclusions can be applied to the regional airfreight sector. This sector will need to consider responding to the specific demands of shippers looking for complete door-to-door services as opposed to simple airport-to-airport services (Park et al., 2009).

SOLUTIONS AND RECOMMENDATIONS

Integration, infrastructure and service reliability are key challenges to be addressed by freight forwarders (including airfreight service providers in regional communities). It is apparent that these three challenges are inextricably bound and cannot be addressed in isolation. Over the past decade, similar challenges in the global freight industry have been overcome by: improvements in the flow of information, (both within an organization and external to the organization); and the application of technological tools and e-commerce. The following section discusses these solutions and their applicability in addressing the airfreight service needs of regional communities.

Improving the Flow of Information

International competition and the demand from shippers for timeliness and flexibility of delivery has forced companies at all stages of the supply chain to consider how they can enhance their competitiveness (Hesse, 2002). In the previous section, we discussed the importance for rural shippers (of high-value, perishable products) to have access and opportunities to book entire services door-to-door through a single platform. In an effort to realistically apply this concept, freight-forwarding companies (including regional air transport service providers) will need to consider integration where key regional stakeholders are able to communicate with and understand the range of freight services available. Thus, an important driver for the development of airfreight services is the requirement for logistics companies to improve the flow of information both internally and externally (Rutner, Gibson, & Williams, 2003).

Information systems have experienced steady growth in inventory management, production and logistics. In global freight networks, the expanding information requirements have facilitated the integration of logistics information systems (LIS) and supply chain information systems. Over the

past three decades, LIS has captured a significant area of study in the field of logistics and operations (House & Jackson, 1976; Whipple, Frankel, & Anselmi, 1999; Williams, Magee, & Suzuki, 1998). Considering the increased application of LIS, one area of research has focused on the evaluation of the ability to integrate logistics and LIS throughout the organization. Integrated logistics refers to the system-wide management of the complete logistics chain as a single entity, instead of separate management of the individual.

A study conducted by Gustin, Daugherty, and Stank (1995) found that companies that have higher levels of logistics integration throughout the organization, are also likely to be using more logistics information systems. Later, Rutner et al. (2003) supported this finding, asserting that companies that have successfully implemented the concept of integrated logistics are also companies that are carefully utilizing appropriate logistics information systems. For airfreight providers serving regional communities, this solution implies that air operators consider integrating businesses through acquisition and mergers with other modes of transport to ensure the door-to-door nature of freight service is effective. Furthermore, this option ensures that information and communication flow and management of the complete freight transport system are entirely centralized.

While this may offer an obvious solution in meeting the integration and service reliability needs of regional communities, this solution requires significant investment in additional transport modes, integrated information system management tools and associated infrastructure. This may be feasible for large freight companies. However, the smaller service providers operating in specific regional locations may find this option prohibitive (Kille et al., 2013). Berger and Schroder (2011) considered this limitation, appreciating that the transport of airfreight from the shipper's door to the door of the consignee is complex and involves a number of collaborating logistics companies (e.g., freight forwarders, road transporters, airfreighters etc). This process involves a number

of individuals who manage their own aspect of the delivery with their own perspectives of the logistics chain. These individual perspectives result in individual decisions which impact on the quality of the delivery and final delivery time.

Considering the reality of airfreight, Berger and Schroder (2011) maintained that information flow continues to be of great benefit to overall service quality. However, Berger and Schroder (2011) argue that efficiencies within the entire door-to-door transport system can be achieved by maintaining the system of decentralized decision-making. Effectively, the approach considers specific criteria that is relevant to each stage of the delivery process and encourages the sharing of critical information required for each aspect of the logistics chain. This allows sensitive information (including price, customer information etc) to be maintained by the local operators and only the most necessary information to be shared along the logistics chain allowing for more effective planning and improved service reliability.

Forster and Regan (2001) conducted a case study analysis of the international airfreight industry in the United States examining the impact of electronic integration in logistics supply chains. The study found that a technologically deterministic perspective of the impact of electronic integration, without considering the contextual influence is misguided in its assumption. In the body of supply chain literature, the discourse associated with relationships between companies is distinguished by language of coordination and cooperation that allow the seamless transfer of information. However, the research of Forster and Regan (2001) advocates that electronic integration must also consider issues of power (influence and domination one company has over the other) and conflict (i.e., competitive, technological or language differences) that influence the amount of information that needs to be transferred between companies.

Decentralized and centralized approaches are applicable in the context of airfreight service needs

for regional communities. The overriding solution, however, emphasizes the need for airfreight service providers to implement systems that allow the gathering and sharing of applicable information across the entire logistics process. While issues of power and conflict between companies will need to be addressed, the implementation of information sharing systems is further supported by the application of appropriate technological solutions and electronic commerce.

Technology: Application of Electronic Commerce

The integration of data and information systems within the entire logistics process has been supported by the development of modern information and communication technologies (Hesse, 2002). Distinct characteristics such as electronic data interchange (EDI), the automation of product flow in dedicated distribution centers and warehouses, or the use of computer-based tracking and tracing systems (offering online awareness of the status and location of the shipment) are only a sample of the principal sources of significant productivity gains over the last twenty five years (Golicic, Davis, McCarthy, & Mentzer, 2002).

The emergence of the Internet has allowed dramatic improvements in the sharing of information in logistics. The costs of web-based inventory management tools have reduced and thus the uptake of such systems has increased (Zillur, 2004). Furthermore, the web has become a common marketplace for internet-based suppliers. The Internet has developed into a significant management tool, not only for the individual companies, but also for controlling the complete producer-shipper relationship (Hesse, 2002).

The term 'electronic commerce' is principally concerned with the exchange of information and transactions between different commercial entities (i.e., business-business electronic commerce) and exchange of information between businesses and customers (i.e., business-to-customer elec-

tronic commerce). Electronic commerce (or e-commerce) transactions can be divided into customer related activities (e.g., receiving orders and marketing) and the business-related activities (e.g. the processing and shipment of the orders).

Rutner et al. (2003) argue that more advanced organizations are beginning to extend their logistics operations to the e-commerce environment through the implementation of internet-based purchasing and extranet-based supply chain management applications. For these companies that have progressed through the integration process, the application and implementation of systems that also support intranet-based activities and communication appears to be an important step towards achieving logistics integration.

Cost is an important driver in competitive industries such as transport and logistics. The enormous economic potential of business-to-business e-commerce to effectively lower costs is dependent on a single factor. That is, the complete break-down and re-organization of the supply chain with cost efficiencies at the heart of the examination (Reynolds, 2000). Many of the common e-commerce applications in freight distribution, manufacturing or retail relate to: order processing and completion; management of inventory; fleet management and vehicle routing; brokering of freight; and electronic payment.

In the case of regional communities, where integration of services is key to the success of the entire logistics process, the evolution of e-commerce is likely to further support the cost saving potential of any integrated logistics concepts. However, integration of systems in the regional airfreight network will continue to be a barrier unless the entire logistics chain is re-examined and restructured to allow essential information to be shared. Never-the-less, e-commerce as a part of the entire distribution system can provide positive outcomes for freight companies, shippers and consumers by allowing higher delivery frequencies over longer distances and enhanced air transport networks (Hesse, 2002).

FUTURE RESEARCH DIRECTIONS

The implementation of e-commerce offers increased levels of support for the integration of logistical operations by allowing improved access to and linkages between varied types of information that are critical to the logistics process. Rutner et al. (2003) argues that as the reliance on such systems continues to increase, it is even more imperative for managers in both the fields of logistics and information systems to strengthen working relationships between the two functions. Effectively, information systems will need to support logistics processes and logistics processes will need to feed in and support information systems.

To what extent business-to-business e-commerce applications are being implemented in freight and distribution systems is not entirely known. Considering the potential benefits, it is assumed that information management and integrated processing of the entire supply chain are used widely, particularly in medium sized and large firms (Hesse, 2002). Additionally, the contribution of e-commerce to a more sustainable and economically viable distribution system is highly dependent on a number of factors including regional circumstances, shipper habits, consumer habits, accessibility of various transport modes, geographic location of the airport and associated facilities, population density and political and governmental support. Future research is required to more comprehensively examine the application of e-commerce in regional freight networks and the impact that these factors may have on the provision of freight services to regional communities.

CONCLUSION

Access to airfreight networks allows regional communities the opportunity to participate in markets that cannot be equally serviced by other modes of transport. For agri-producers focused on the production of high-value, low weight products, this

means access to appropriate freight services with the ability to transport products efficiently and effectively from the shipper's door to the consumer's door. Thus, examining the needs of regional communities with regards to airfreight access is a principal concern in developing and fostering sustainable economies for these communities. This article has discussed the airfreight challenges facing regional communities and explored their needs for integration, infrastructure, and service reliability. Information sharing and the application of appropriate technological tools lie at the heart of these challenges. In discussing the shifting demands of consumers and the emergence of the Internet, the authors contend that these logistics challenges can be overcome by: improving the flow of information and communication between businesses in the entire distribution system; and applying e-commerce tools to assist in integrating systems and sharing of information.

KEY TERMS AND DEFINITIONS

Electronic Data Interchange: The electronic interchange of business information within a standardized format. This process then allows one business to send information to another business electronically and without paper.

Logistics Information Systems: A subset of an organization's entire information system, and is focused on the particular issues associated with logistics decision-making.

Virtual Learning Environments

Creating Active Learning Spaces in Virtual Worlds

Reneta D. Lansiquot

INTRODUCTION

Virtual reality can advance educational practices, as creating active learning spaces in virtual worlds offers a more natural way to promote interdisciplinary studies that integrate play to engage students (Lansiquot, 2015, 2012; Lansiquot, Cabo, & Cunningham, 2016; Lansiquot & Cunningham, 2016; Lansiquot, Liou-Mark, & Blake, 2015). Role-play can facilitate engagement in interdisciplinary courses for technology students. This chapter will detail how role-playing in virtual worlds can be used effectively to support interdisciplinary studies and place-based learning, extending learning in undergraduate urban technology classrooms.

As educational technology becomes more of an emergent field and more colleges are progressing towards implementing various forms of technology in their curriculum, it is to be expected that the use of virtual worlds will become more predominant. Many colleges are trying to find the perfect way to integrate virtual worlds in order to create a unique learning tool for students to grasp how vast the virtual space can be. However, virtual space has been used in many other ways for a multitude of purposes that are not limited to just teaching. For digital games, there have been many attempts to utilize virtual worlds in order to create an immersive game where the players can experience the game in a complete way. Virtual Boy, released in the United States

on August 14, 1995 by the Japanese gaming company, Nintendo, and discontinued March 2, 1996, provided a jarring, immersive virtual reality headset that was clunky and considered obsolete quickly. At the time, however, it proved to be a sufficient stepping stone in order to make the changes to create a better excursion into the virtual world. In the present, there is the Oculus Rift, released in 2016, with a newer virtual reality headset which is a strong foray into an all-around immersive look into a game in which the players are avatars who can manipulate the game as they would in real life.

In addition to its use in games, the virtual world and its massive space are used in training simulations for various professions. For example, the United States Army has implemented virtual training models in a bid to offer a more complete and effective training simulation. The benefit of this simulation is that it offers no harm to the soldiers, who can train as long as they want without risking the physical harm that real training can cause. Also, the simulation can be safely managed and edited so the training experience can be varied, and soldiers can learn how to deal with multiple scenarios. Because the virtual world is so vast and moldable, it can take whatever form its creators have in mind. Thus, the virtual world and its endless possibilities as an educational technology tool are the artist's virtual clay—if we can only find the right angle with which to approach it.

BACKGROUND

Student learning depends on the ability to create, reflect on experiences, construct understanding, generate rules, and make sense of experiences (Piaget, 1973; Anderson & Krathwohl, 2000; Bruner, 2007). Building on this constructivist perspective, a crucial component of dynamic interdisciplinary studies is problem-based learning, an educational approach that offers the potential to help students develop flexible understanding learning skills. Problem-based learning can also be an effective method for improving classroom engagement (Ahlfeldt, Mehta, & Sellnow, 2005; Duch, Groh, & Allen, 2001). Students learning by solving problems must understand and apply concepts while becoming proficient at new skills. They collaborate to identify what they need to learn in order to solve a problem. They engage in self-directed learning, apply their new knowledge to the problem, and reflect on what they learned as well as the effectiveness of the strategies employed. Rather than simply lecturing and testing students on what was said in lecture, instructors facilitate the learning process by guiding, monitoring, and supporting (Vygotsky, 2006), helping students develop flexible knowledge, successful problem-solving skills, self-directed learning skills, effective collaboration skills, and intrinsic motivation (Hmelo-Silver, 2004).

Student learning can be further improved by adding an interdisciplinary component to courses incorporating collaborative problem solving (Cabo & Lansiquot, 2014; Lattuca, Voigt, & Fath, 2004; Project Kaleidoscope, 2011). Interdisciplinary courses encourage students to connect purposively and integrate cross-discipline knowledge and skills to solve problems in ethically and socially responsible ways. In order to comprehend factors inherent in complex problems, students must synthesize and transfer knowledge across disciplinary boundaries while becoming comfortable with complexity, uncertainty, and varied perspectives. The process

demands that they think critically, communicate effectively, and work collaboratively. An innovative and effective way to address technology learning goals is to facilitate interdisciplinary studies via virtual worlds—multi-dimensional spaces composed of communities of practice in which people can establish a sense of presence, learn, socialize, and collaborate (Lave & Wenger, 1991; Schroeder, 2008; Spence, 2008; Downey, 2012).

These interdisciplinary virtual worlds are so effective because education and technology are continually interconnected, and both possess the ability to transform the world in which we live. Virtual worlds are allowing people from a variety of disciplines to create simulations for purposes that fall directly in line with their teachings. Medical virtual reality groups have devoted time to the study and advancement of simulation technology for clinical purposes, and they explore treating mental health as well as the improving motor and cognitive skills. Not only are virtual realities used for professional purposes, but they are also used to gauge patient progress in, for example, social skills. Research has found that students who struggled to become a part of a class group found it far easier to gain acceptance from their peers through the virtual realm, which made it easier for them to collaborate, instilling confidence in them and increasing their motivation. Where the real world has limitations on what can and cannot be done, the ability to introduce practical knowledge to the classroom through a means of fantastical three-dimensional effects makes the educational experience invaluable. Students are able to engage in a hazardous environment (like a construction site) and get a feel for what should and should not happen under drastic conditions, all in the safety and comfort of a classroom. The process is rewarding, and the reward in terms of self-improvement makes incorporating interdisciplinary virtual worlds all the more worthwhile (Abrosimova, 2014).

VIRTUAL PLACE-BASED LEARNING

Issues, Controversies, Problems

When the idea was first introduced, many instructors found the notion of using commercial virtual worlds appealing, but the excitement for these types of spaces died down as educators felt that their visions for the worlds could not come to fruition. Consequently, higher education institutions decided to design their own spaces in order to improve their contextualizations of collaborative learning in three-dimensional virtual worlds. Open Cobalt (2016), for example, is a free application that caters to the construction and facilitation of game-based learning spaces on which students and educators alike play guest to a network of interconnected collaborative spaces in which they can interact and learn from one another. While it is not nearly as popular as its counterpart virtual engine, Second Life (2016), a plethora of colleges have made use of the world and its facilities. OpenSimulator (2016), another virtual engine available for academic exchanges, provides colleges with the opportunity to access, set up servers, and provide virtual classrooms for learning (Young, 2010).

Second Life remains one of the most frequently used virtual worlds in the educational field because, “as the largest-ever 3D virtual world created entirely by its users,” it enables opportunities for distance learning and real-time communication. The effectiveness of this virtual world is supported by research: A study of student learning preferences in virtual worlds concluded that a great number of students are visual learners, and using Second Life is a viable way to cater to those students by implementing its vast space (Mabrito, 2012). And while this commercial space holds much promise for the promotion of distance learning and the processing of new information in an engaging and rewarding manner for the students, its potential can only be realized if the educators utilize the space properly. Treating the space as if it were just a recreation of a classroom

diminishes this potential by stifling the creative space that both the educators and students access.

Second Life can be a particularly effective virtual world for educating students. Launched in 2003, it is appealing in many ways. Because it is easy to learn, has highly customizable avatars, and users are able to manipulate objects and add interactivity using the Linden Scripting Language (LSL), it seems to be an ideal educational technology. However, the way that a majority of educators have used this space is very limited. Instead of using this virtual world as a means of teaching students by letting them create relevant objects, many educators have recreated their campuses and classrooms, where the most interaction that the students have is interacting with each other and reading lessons from in-world objects (e.g., slides placed on a virtual screen). In the real world, we are bound by natural laws to which we must abide; in virtual worlds, on the other hand, while there are still some laws that exist inherently by the creators of that space, students are otherwise not bound by natural laws. For example, in Second Life, student avatars can change their looks immediately, or they can teleport from one side of the world to the next. Students can even fly! The myriad possibilities seem almost endless in this space, only limited by the imagination of the ones who utilize it. Unfortunately, too often the only worlds that were created were fantasy settings of campuses. Because of this misunderstanding of the possible uses of Second Life, the number of educators who wanted to use it declined considerably. They looked to other virtual spaces that suit their needs or decided to build their own. Others just found that Second Life was too clunky, and the fact that it used its own created LSL instead of a pre-existing language—such as JavaScript or C#—educators decided that it was not worth the hassle of exploring the space. Further, the eclectic community itself was less than ideal for educational purposes. Still, there have been some who have been able to grasp the possibilities of Second Life and use it, for example, to facilitate virtual place-based learning. For example, geoscientists

can use it to allow students in urban classrooms to explore different environments and role-play as scientists climbing up a mountain, collecting data (see Lansiquot, Liou-Mark, & Blake, 2015). Thus, there are still educators who are effectively using this virtual world as a learning space, but recruiting and teaching them to use this is understandably difficult.

Solutions and Recommendations

To graduate with a bachelor's degree, students at New York City College of Technology (City Tech) must take an interdisciplinary team-taught course. Courses such as *Weird Science: Interpreting and Redefining Humanity* allow students to create their vision of the future of humanity. The course explores the enduring question, "What does it mean to be human?" It exposes students to a spectrum of ideas and attitudes from the sciences, technology, and engineering, familiarizing students with concepts from these disciplines. The course highlights complementary perspectives. For example, students are introduced to the anatomy and physiology of the cell while reading nonfiction literature designed to appeal to the imagination (Lansiquot, 2015; Lansiquot, Blake, Liou-Mark, & Dreyfuss, 2011). Students question how different disciplines define concepts of the self and disrupt or disturb seemingly stable identities. The course focuses on being virtually human.

Weird Science utilizes the *Visual Understanding Environment* (2016) for concept mapping, in addition to *Second Life*, which acts as a space for students to get a better understanding of multiple disciplines. By considering the question of what it means to be human, students are tasked with creating physical representations of their opinions. Initially, students were asked to present a possible idea of where humanity may end up in the distant future. Using the knowledge they gained from a dozen guest lecturers from various disciplines—from biology and computer science to economics and sociology—students come up with a plausible path that humanity would follow.

Students are then grouped and asked to build a physical representation of their ideas on City Tech Island, a space in *Second Life*. From there, students create interactive simulations. This is already much different than the way that many educators use virtual worlds. Instead of treating the island as a fantasy recreation of the City Tech campus and having the students sit and read a lecture in one of the many classrooms, essentially creating an online seminar, students are in charge of manipulating the space and using it as a way to express their visions on what they believe is humanity at its highest (or lowest) points in the future. Students test the boundaries of what they can do in this virtual world, and they treat the space as it is meant to be: moldable clay that can be shaped into whatever their imagination can come up with. And as such, City Tech Island has housed many creative ideas: From an underwater civilization to an interactive museum where the avatars are teleported to different recreations of historical sites, all of which occurs when students take full advantage of the virtual space. These projects help demonstrate that students were able to get a grasp of the essence of the class, but there was still a way to go before it could become a stronger and more integrated learning space for the students. Currently, student projects are designed in *Second Life* and spiral out in whatever direction that the student can justify. Although the fact that they could use their imagination was a boon, it was also a detriment, since the students had little restriction on what their futures could be.

FUTURE RESEARCH DIRECTIONS

The second iteration of the group project involves integrating the disciplinary perspectives of the guest lecturers more explicitly. The new project is composed of three parts: the proposal, the engineering of the idea, and the presentation. For the proposal, students present an idea of where they think humanity is going based on the combination of two or more disciplines. For example, one

project could combine the insights of psychology and physics into the idea that, in the future, humanity would develop a way to heighten visual perception to see more into the quantum world, the physics of which, presently, we are not able to see with the naked eye. This could be represented in Second Life by a pair of glasses that avatars can put on, enabling them to see molecules surrounding them as if they were as small as the various subatomic particles. By setting up the project this way, students are able to treat the activity more as interdisciplinary learning, thinking about each discipline and considering how each lecture can complement each other in a way to make a seamless project. Not only that, but the project also relates to their final paper, which is a paper that answers the same enduring question: What does it mean to be (virtually) human?

CONCLUSION

Students need a space where they can learn without fear of penalty, and effective pedagogies for interdisciplinary studies can supply it. An effective approach to teaching should facilitate active learning, foster effective problem-solving strategies, promote progressive collaboration, and provide an environment that requires creation. Virtual worlds offer telepresence, synchronous online learning, as well as opportunities for co-construction, collaboration, and exploring impossible environments. To help students to understand the big picture of complex applications, they should be engaged in process and application early and learn from play, as play involves simpler models of work. This is especially important in complex three-dimensional modeling. Alternatively, simpler models of existing technologies that teach process, collaboration, and creation can be used to engage students before attempting to teach rich, deep, powerful, but complex applications. As a result, students will be able to understand the big idea first. Using virtual worlds with simpler techniques empowers students

to understand process and implementation. An added bonus of this setting is that student success is immediately demonstrable.

These complex modes of thinking were stimulated by the scaffolding of assignments requiring collaborative interdisciplinary studies in Second Life, and simulating the future in Weird Science, a writing-intensive interdisciplinary team-taught course based on the enduring question of what it means to be human. Within this context, research opportunities for students include exploring how best to integrate disciplinary perspectives and represent these in virtual worlds. What are the implications for student engagement, retention, and graduation? Interdisciplinary collaborations enable educators to cultivate an ongoing relationship of learning, dialogue, and challenge. Promoting interdisciplinary studies necessitates creating active learning spaces in virtual worlds to support and engage students.

KEY TERMS AND DEFINITIONS

Digital Game: An electronic creation, recreation, or adaptation of a game; a type of play activity where the participants agree upon a set of rules that they follow and is decided by luck, skill, or strength.

Interdisciplinary Studies: Learning that focuses on questions, problems, and topics too complex or too broad for a single discipline or field to encompass adequately. These studies thrive on making connections among seemingly exclusive domains.

OpenSimulator: An open-source multi-platform, multi-user three-dimensional application server.

Second Life: A three-dimensional virtual world where every avatar is a real person and every place is created by residents.

Virtual Reality: A computer-simulated recreation of a real-world environment that allows users to more fully immerse themselves in the simulation.

Virtual World: Representation in an artificial system or a part of reality.

Visual Understanding Environment: An open-source tool for managing and integrating digital resources in support of teaching, learning and research; it provides a flexible visual environment for structuring, presenting, and sharing digital information.

Developments in MOOC Technologies and Participation Since 2012

Jeremy Riel

University of Illinois at Chicago, USA

Kimberly A. Lawless

University of Illinois at Chicago, USA

INTRODUCTION

Massive open online courses (MOOCs) are a recent approach to education, with much buzz generated around them by technology investors, educators, and the news media alike (Dolan, 2014). At the height of MOOC emergence, The New York Times proclaimed 2012 as “The Year of the MOOC,” with MOOCs hailed as the singular approach that would save higher education’s crises and educate the world using Internet-based technologies (Pappano, 2012). However, despite the hype and the subsequent enrollment of millions of learners into MOOCs, the following years experienced a reversal of energy as the results of studies on the effects and costs of MOOCs began to reveal that MOOCs were not a panacea to formal education’s challenges (Dolan, 2014; Liyanagunawardena, Adams, & Williams, 2013). Over the last two years, partnerships between universities and MOOC providers have become strained as outcomes of these courses remained ambiguous (Kolowich, 2013a, 2013b). Now, in 2016, as MOOCs continue to serve millions of students and there are more courses available than before, key questions persist about the efficacy, relevance, and value of MOOCs.

This chapter examines the state of MOOCs between 2012 and 2016 and discusses advances in knowledge around MOOCs that have been observed from empirical research during this period. We build upon our previous review of MOOCs

that was originally written in 2013 (Riel & Lawless, 2015), as a large number of studies focused on MOOC technologies, efficacy, and goals have been published in the short time between 2012 and 2016.

BACKGROUND

Characterizing MOOCs

MOOCs have gained notoriety primarily due to the massive number of participants (DeBoer et al., 2014; Dolan, 2014). While conventional college courses might host hundreds of students, MOOCs have the capability to host hundreds of thousands of students simultaneously with usually just one instructor. However, despite the benefits of reaching a large number of learners, educational researchers have been concerned with the loss of in-person interactions that are known to be beneficial to learning in higher education (Wiebe, Thompson, & Behrend, 2015; Kop, Fournier, & Mak, 2011).

Openness in the case of MOOCs refers to exclusivity or the ability of learners to access the course. In essence, anybody can “attend” the class without having been formally admitted to an educational program, which is one of the primary draws of the MOOC movement (Dillahunt, Wang, & Teasley, 2014; Morgan & Carey, 2009). The “open” policy does not mean all MOOCs are free of cost,

however. Some courses allow anyone to enroll, but charge a fee to receive certain services. For example, MOOC providers often offer premium certificates of completion and dedicated coaching services for a fee. All MOOCs operate on the Internet to some degree. While some MOOCs have been designed to incorporate in-person meetings of students, such as local study groups, all materials and interactivity within a course are generally facilitated online. Many formal college courses now also occur parallel to MOOC courses, with some activities performed in physical classrooms and some performed online (Agarwal & TED, 2014; Collins et al., 2013).

Perhaps the most defining element of a MOOC is that they are centered on a course of study. MOOCs are generally real-time, organized events in which participants are time bound on a course of study around a topic with deadlines and a syllabus (Spector, 2014). This is in contrast to other learning technologies on the Internet, such as articles and text resources, professional learning communities, and tutorials. Participants can ignore course trajectories based on their interests. The diversity of ways in which participants use MOOCs have led to research on course and curricular sequence in MOOCs (Collins et al., 2013; DeBoer et al., 2014).

Technologies Used in MOOCs

Although a MOOC is often referred to as a singular technology, they rely upon a combination of digital applications to achieve their intended functions. These functions serve to deliver content and information to participants, connect participants with other participants and the instructor, and facilitate activities and interactions that promote learning. The digital applications include:

- **Learning Management Systems:** Learning management systems (LMS), also called course management systems (CMS), are web-based applications that are designed to manage and deliver content to partici-

pants within an online course. Many LMS provide a place to host course content, provide an interface for interactive activities for participants, and keep a record of learners' participation.

- **Multimedia Information Delivery:**

MOOCs are predominantly comprised of video-based lectures and reading materials that can be accessed at a student's own pace within the timeframe of a course. Instructors often record lectures they would give in a conventional classroom and distribute these videos to the online course. Instructors also provide background readings or texts, links to websites, images, and other relevant videos or audio.

- **Interactive Elements / Activities for Creativity and Publication:**

Many MOOC instructors intend for participants to be actively engaged in courses instead of simply watching a series of video lectures. When instructors assign projects to students, students have better opportunity to "learn by doing." Active learning is when a student is engaged on creating or interacting with an authentic project related to the course instead of passively receiving information via text or video. Active learning strategies are supported by technologies that promote creating and publishing documents and media, writing blogs, and wikis. Active learning is supported by allowing students to pose questions to one another, share ideas, and collaboratively develop a better understanding of course topics.

- **Notifications:** It is important to provide students with regular reminders and notifications about new content within a MOOC. To address this, many MOOCs provide regular notifications to participants via multiple media (e.g., text/SMS, email, popups) whenever certain events occur within the course (e.g., new content uploads, comments on others' work, availability of a new activity is available).

- **Exams, Quizzes, and Problem Sets:** Students and instructors desire indicators of progress toward course objectives. Much like a conventional course, MOOCs employ quizzes, exams, and problem sets to assess whether participants understand course concepts or can perform certain skills. Many of these evaluations are automated, as well.
- **Progress Tracking and Badges:** Feedback on progress in a course is a helpful indicator for participants. MOOC designers include feedback on a participant's level of interaction in the course by providing badges, which are digital graphics that are "awarded" to participants to indicate completion of course objectives or the degree to which they have participated.
- **Learning Analytics:** Learning management systems typically employ learning analytics that track participant activity and provide statistics on how participants approach course content and activities. Sophisticated learning analytics can include analyses on how long participants view materials, the paths they typically take to complete a task, how frequently and for what purpose they communicate with other participants, and which resources they find valuable.

Interacting With MOOC Technologies

One way that researchers examine the design and efficacy of MOOCs is by investigating the structural aspects of a MOOC. In this common type of research, the focus is on the use and characterization of a particular design element, and researchers seek to explain how and why a design element is used. Researchers investigate the ways in which learners participate with various elements in a MOOC and how these participation patterns are related to psychological, demographic, or environmental variables and indicators. For instance, Milligan, Littlejohn, and Margaryan

(2013) identified similarities between MOOCs and other formats of online learning, with "lurker" or non-participatory behavior occurring in almost all cases of MOOC participants who had opportunities to post assignments, access course materials, or participate in discussions. Perna et al. (2014) emphasize that learner goals predict MOOC element use as well. In their study, they investigated 16 Coursera courses and identified that students' goals and completion predict their progression through courses. Higher numbers of interactions with MOOC elements are also positively correlated with learning skills, as participants who use interactive features are those who report a high level of self-responsibility and established personal goals, have good time management skills, and are consistent in checking the course for updates (Dearnley, 2003; Rodriguez, 2012).

Social interactions are a particular form of participation that are emphasized within MOOCs. It is difficult, however, for instructors to develop learning communities within MOOCs (Gillani & Enyon, 2014). The use of message boards and forums remains very low according to individual MOOC reports, with one study citing that only 3% of participants post to a public forum (Breslow et al., 2013). This number increases for students who complete course objectives, with 52% of course-completing students using public forums. In addition, there was an increased use of forums and message boards during course projects and exams, confirming that already-published material is used by more than just those who actively participate on forums. However, forums in courses are not the only tool for social interaction. An example of this is illustrated with how Shen & Kuo (2015) examined the social media use of MOOC students, particularly those who used Twitter during their courses. Using social media mining techniques, they found that participants' questions and restatements of key ideas were shared more frequently (retweeted), which signified importance. Also, students' sentiment toward a course, as expressed via their social media feeds (e.g., positive, neutral, or negative sentiment), play an important role in

MOOC participation. These studies illustrate that MOOC participation can be done in isolation, but is highly complimented by social interactions and the ability for students to express their questions, ideas, and concerns.

MOOCs are also natural experiment sites for new technologies and interactive features. MOOC platforms typically have the opportunity to collect significant user feedback and participation data as a result of thousands of simultaneous participants in a course. However, novel technologies are not the only interactive elements that have recently been examined. Guo, Kim, and Rubin (2014) explored the assumptions around publishing digital video for online courses, which are a staple of online course communications and activities. By using data from millions of video-watching sessions in MOOCs, they demonstrated that the length, composition, and production value of video matter in MOOC achievement. For instance, they found that the peak length that any video is watched is around 6 minutes, regardless of full length of a particular video segment. In addition, production value on video, such as the quality of filmmaking, lighting, and scripting, was related to achievement. However, they also found that large investments in film quality did not make a difference, instead recommending a middle ground in production quality. Similarly, Li, Kidzinski, Jermann and Dillenbourg (2015) examined fast forwarding and pausing with video. They identified many distinguishable patterns of pausing and fast forwarding based on students' level of expertise with the material under study, indicating that the ways in which students use video reference material might be different based on their incoming academic characteristics. These findings indicate that even the most common MOOC technologies have many opportunities for improvement and that additional supports can be identified, tested, and implemented with learners based on their needs, perhaps dynamically.

Interactions with course materials and elements are the drivers of learning in MOOCs. Scholars and designers agree that engagement in

MOOCs should be promoted in order for learning to occur, but finding the proper combination of interactive design feature, pedagogical approach, and course content remains a challenge (Hew, 2014; Hrastinski, 2009). However, there are many ways to measure engagement with online learning activities (Henrie, Halverson, & Graham, 2015). In a recent study, DeBoer et al. (2014) suggest a focus on specific research variables for studying MOOCs, such as level of participation in activities, achievement, curriculum sequence, and time. These suggested variables leverage the capabilities of MOOCs to capture digital logfiles of participant interactions to better understand how technologies are used for learning and how learners interact with MOOC technologies (DeBoer et al., 2014). With data that potentially spans millions of users, researchers can better identify connections between engagement, goals, and outcomes within MOOCs and other online courses (Henrie, Halverson, & Graham, 2015).

MOOCs and Achievement

Another method of studying MOOCs is to focus on students and the processes of learning within MOOCs, as opposed to examining the technologies themselves. Learning and achievement in MOOCs is most often measured by course completion. However, low completion rates have been a consistent headline concerning MOOCs. A prominent example of low levels of completion occurred in 2013 when San Jose State University partnered with Udacity to provide online-only courses for credit for their students. Low course passage rates in the 20-30% range for three courses in this pilot experiment prompted school officials to suspend any future MOOC courses (Collins et al., 2013). However, at the same institution, a partnership with edX proved to be fruitful. In a "blended course" model in which MOOC content was used in traditional, face-to-face courses in lieu of textbooks, a STEM course that had a 41% failure rate was reduced to 9% during a MOOC-blended pilot program (Agarwal & TED, 2014). While the issue

of high drop rates remains a persistent problem, the initial evidence for using MOOC materials complementarily in a blended, face-to-face course is encouraging to educators.

Completion, however, is not the only indicator of learning. Academic achievement in MOOCs is typically expressed as grades or percentiles in MOOC courses, similar to traditional higher education. In an effort to predict achievement outcomes, Greene, Oswald, and Pomerantz (2015) investigated connections between achievement and various affective and demographic factors in MOOC students. They found that the higher students' personal expectations of how much time they would spend on a course as well as students' level of prior educational experiences were predictors of achievement. Similarly, Terras and Ramsay (2015) examined psychological factors that influence students' achievement in MOOCs, finding that self-regulation skills, perception of time, and level of motivation are all critical factors that lead to achievement. To address limitations of studies that look at a single moment in time, Wang, Paquette, and Baker (2014) studied students' achievement in MOOCs as related to their career growth. They found that students' career goals were persistent indicators of student achievement over time. As students' goals change or are amended, the level of participation and achievement in MOOCs also changes. Wiebe, Thompson, and Behrend (2015) suggested that students' goals and motivations should be a primary focus in MOOC studies due to these factors' strong influences on learning and MOOCs' open invitation to learners with diverse interests.

These studies illustrate that cognitive skills such as goal setting, time keeping, and setting expected levels of effort, as well as affective factors such as motivation and interest all play significant roles in MOOC achievement. These findings also indicate that students who are used to traditional higher education methods and have done well in traditional higher education are more likely to succeed in a MOOC. This can be problematic as MOOCs attempt to reach potential students who

have not been highly represented in traditional education.

Who Uses MOOCs?

At their rise, the key promise of MOOCs was to open access to learning materials and courses to people who have otherwise been unable to participate in formal higher education. In the last two years, multiple studies have been published that shed light on the fulfillment of this goal. In early assessments of MOOC participation in individual courses, students from countries from all over the world were represented. In a study of edX's first STEM-focused MOOC by Breslow et al. (2013), students from 194 countries participated. In the same study, enrollment in this MOOC (a course on electronic circuits) was predominantly male (86%), the median student age was typically between 20 and 30, and no significant relationships were found between gender, age, and course completion. Additional studies of other STEM related MOOCs echo these patterns (Belanger & Thornton, 2013; Ho et al., 2014). However, in studies on non-STEM-oriented courses, higher levels of female participation were observed (Collins et al., 2013; Ho et al., 2014). This evidence suggests that course material follows general societal trends in levels of participation by gender, despite being openly available. As they mature, MOOCs may serve a role in increasing access to and interest of subject areas that traditionally see low levels of participation by female and older students.

In addition to increasing opportunities for broadening educational access based on gender, it is often cited that MOOCs have the potential to be particularly transformative for learners in countries other than America, where most MOOC providers are headquartered. Although students participate in MOOCs from all over the world, however, most MOOC content is provided only in English (Agarwal & TED, 2014; Breslow et al., 2013; Ho et al., 2014). To address the issue of language, the major MOOC providers integrate captioning technologies into their platforms. For

instance, edX's platform simultaneously displays a transcript alongside video as it is playing, and users can toggle between available languages. Morgan and Carey (2009) identified some benefits of international participation in a study of rural students who had difficulty accessing brick and mortar higher education campuses in Mexico, Russia, and Canada. They found that students in the study strongly benefited from interacting with students from other cultures and economic backgrounds. Dillahunt, Wang, and Teasley (2014) performed a similar study of underrepresented international students in a MOOC by asking questions about completion of MOOC courses. They found that although the students in underrepresented groups did not complete MOOC courses at a higher rate than students in traditionally represented groups, the students in underrepresented groups that did complete the course completed with distinction at the highest rates. These studies illustrate that international students are motivated to participate in MOOCs, but much work still needs to be done to achieve the potential of far-reaching MOOCs.

FUTURE RESEARCH DIRECTIONS

Studies on MOOCs have been published in prominent academic journals in recent years as data on them became available. Common among recent research are case studies and institutional reports of individual MOOC courses (e.g., Belanger & Thornton, 2013; Breslow et al., 2013; Collins et al., 2013; Ho et al., 2014; Liyanagunawardena, Adams, & Williams, 2013). Due to the large number of single-course case studies by 2013, the research community encouraged more robust investigations of relationships between student learning and the various design aspects of MOOCs (Velesianos & Sheperdson, 2015; Wiebe, Thompson, & Behrend, 2015). As technologies continue to improve each year, future studies should focus on understanding the behavioral and participation patterns of students (DeBoer et al., 2014; Perna et al., 2014), the learning processes of students in MOOCs

(Wiebe et al., 2015), and the design and efficacy of student supports in MOOCs (Dearnley, 2003; Kop, Fournier, & Mak, 2011).

In addition to researchers, grantmaking institutions also play a significant role in the future of MOOC research. To examine the priorities of grantmaking institutions, Gašević et al. (2014) studied 266 proposals submitted to the MOOC Research Initiative in 2013 to identify the directions that MOOC research was heading at the time. They found that the most frequent proposals were those that investigated social networks and communities underlying MOOCs. In the case of social technologies, MOOCs are an excellent context for research due to their online nature. They also identified other types of proposals for MOOC research, which included ideas for examining student behavioral patterns, technology improvements, learning processes, and the integration of MOOCs into higher education institutions. All of these trajectories continue to be productive areas of MOOC research today, as new interactive capabilities continue to be developed.

As a result of an emerging body of research around MOOCs, education scholars have suggested some guidelines in conducting future MOOC research. Raffaghelli, Cucchiara, and Persico (2015) examined the methodological strengths and shortcomings of recent peer-reviewed MOOC research and found that most studies over the last five years rely on theoretical analyses and case studies that span across multiple epistemological perspectives in a somewhat incoherent fashion. In order to promote consistency in future studies, they suggest that researchers consider approaches to MOOC research that consider how valid theoretical perspectives are connected, such as simultaneous foci on technology and on learners. However, Wiebe, Thompson, and Behrend (2015) argue that researchers must always consider the learning processes and experiences of the student, since learning is the primary intent of a MOOC. From their argument, studies should not only focus on singular variables, but also consider students as a whole unit in order to get a clearer picture. In other

words, there is no one way to study MOOCs and the research community will only get a full picture with multiple perspectives that are woven together. In particular, interdisciplinary approaches that examine MOOCs from multiple perspectives are growing and will be particularly valuable in the future (Veletsianos & Sheperdson, 2015).

CONCLUSION

MOOCs have been primarily studied in two ways. In one approach, researchers focus on the role, effects, and structural traits of MOOC technologies, and investigate participant interactions with particular technologies. In the second approach, researchers examine the processes associated with learning within MOOCs as a context. Researchers of this approach are concerned with psychological, social, and behavioral aspects of MOOC participants. Neither approach is the “right way” to conduct studies, and both are necessary to fully understand the complexity of MOOC learning (Weibe, Thompson, & Behrend, 2015).

Researchers have significantly advanced the field of MOOC scholarship in the last four years. The latest findings on learners and MOOC technologies suggest that MOOC developers and teachers should promote higher levels of participation in activities, as learning is an active process and students need meaningful interactions in order to learn (Hew, 2014; Kop, Fournier, & Mak, 2011; Milligan, Littlejohn, & Margaryan, 2013). However, designers should carefully consider the activities that participants will be expected to do in a MOOC. Activities should be purposefully chosen to match the content being studied and ensure that they are pedagogically appropriate to support student learning. Since behaviors are connected to psychological and social processes underlying learning, online learning participation patterns in their various forms provide an excellent, low-cost window to understanding the learner (Hrastinski, 2009).

MOOCs have come a long way in the last five years, but much work still remains to be done to ensure that technologies are developed to empirically improve learning in MOOCs. “The Year of The MOOC” has come and gone, and many benefits have been demonstrated in subsequent studies. However, MOOCs have not yet achieved the goal of increasing access of people from socio-economic backgrounds that do not traditionally have high levels of access to MOOCs. Course providers should increase their efforts to promote MOOCs to students other than those who traditionally attend higher education. Promoting MOOC access includes designing interfaces that meet the needs of underrepresented students. It is imperative that MOOCs do not simply serve as low-cost replicas of classrooms by using flashy, novel technologies. To simply mimic traditional classroom practices could risk the exclusion of the the best evidence-based practices of teaching and learning.

KEY TERMS AND DEFINITIONS

Active Learning: Experiences that require learners to actively participate in activities, to reflect on their experiences, and to interact with technology and other people in order to develop a deeper understanding of a subject.

Badges: Digital graphic icons that are “awarded” to participants in online spaces to indicate degrees of participation within the environment or completion of objectives within the environment.

Certificates of Completion: Documents issued by MOOC providers that certify that a

participant has successfully completed a course, usually for a fee.

Learning Analytics: Combined automatic data collection and analysis that tracks participant activity and provide statistics on how participants approach course content and activities.

Learning Management System (LMS): Applications that are designed to manage and deliver content to participants within an online course.

Massive Open Online Course (MOOC): An online educational course that is open to anyone to participate, often free of cost.

INTRODUCTION

The purpose of this chapter is to (1) understand MOOCS, massive online open courses, and differentiate MOOCS from other like learning and training methodologies, (2) comprehend the manner in that MOOCS can be utilized, as well as the (3) lasting impacts of MOOCS on learning whether in academics or the corporate environment. MOOCs are aimed at large scale participation in online education (Bud, Smith, & Reisman, 2015). This chapter will identify for educators, administrators, and practitioners the staggering awareness of the outcomes of this learning modality. MOOCs are continuing to change the way individuals receive education and learn. One idea of MOOCs is that learners may learn through collective education using what is believed to be a form of experimentation wrapped in andragogy, adult learning, andragogy. Education through Knowles' adult learning, offers the notion of learners gaining knowledge and understanding through (a) self-directedness, (b) need to know, (c) use of experience in learning, (d) readiness to learn, (e) orientation to learning, and (f) internal moti-

vation (Knowles, 1979; Taylor & Kroth, 2009). Another view is that MOOCs could be the answer to the economic concerns faced by institutions of higher learning, the push to increase learner enrollment, and the drive to enhance graduation completion rates (Ng'ambi & Bozalek, 2015). Administrators, educators, and practitioners are faced with the increased popularity of MOOCs. The popularities of MOOCs include the positives as well as the concerns: their impersonal nature, numerous students enrolled into an individual section of a MOOC course, instructors serving as facilitators, as well as there being no instructors assigned to courses. MOOCs, post-date open courseware which was on the increase in 1990s and the sharing of courseware online. Specifically, open courseware stems from face-to-face instructions wherein instructors share aspects of their courses on the Internet which may be reading lists, assignments, recorded videos, audio lectures, or syllabi. One of the understood top aspects regarding MOOCs is that these courses fulfil knowledge gaps for learners. MOOCs propose for the learners the alternative of completing quality courses without a financial obligation. Some MOOCs

DOI: 10.4018/978-1-5225-2255-3.ch687

courses, like Coursera, offer certificates. With this said MOOCs offer inexpensive avenues to add certificates to learners' resumes and therefore ways to drive personal accomplishments. MOOCs have maintained a large following of users. They draw attention and remain the element learners need to study and become educated outside of the traditional classroom.

This chapter will delve into key significant areas. First, the researchers will gain understanding regarding the development of a method in which Open Source Software (OSS), open source technologies, and open access literature can be incorporated to strengthen the MOOC environment. Second, readers will garner comprehension of how to strengthen the MOOC environment and therefore increase retention in addition to increasing enrollment in higher education. Third, the lasting impacts of MOOCs will be described, mainly as the impacts relate to STEM, Science, Technology, Engineering, and Mathematics and how such programs are entering the online space. Through this chapter, educators and administrators will grasp an increased interpretation of the technologies that have influenced learning and development. Administrators and Practitioners will learn meaningful solutions about open technology solutions so that as-is and to-be MOOCs can be improved with minimal cost. Further readers, researchers, administrators, and practitioners will learn how to infuse MOOCs learning and training initiatives to ensure best outcomes in the academic and e business world.

BACKGROUND

MOOCs is another form of distance education and learning community; the term originated in 2008 by David Cornier and senior research fellow Bryan Alexander (Martin, 2010). At that time, MOOCs described a course entitled *Connectivism and Connective Knowledge* (Pence, 2012). According to Caulfield, Collier, and Halawa (2013), MOOCs

stem from the category of online connected learning communities. MOOCs are representative of Siemens' and Downes' connectivist learning theory, which provides that learning occurs through connections within networks (Pence, 2012). The model uses a network with nodes and associations to explain learning (Siemens, 2013). The name MOOC was derived because (a.) MOOCs are collaborative with the appearance of experimentation, (b.) the courses move along numerous paths, and (c.) MOOCs necessitate participation in "Massively Multiplayer Online Game (MMOG)" (Pence, 2012, p. 27).

MOOCs, a recent innovation in the distance education field, were labeled as disruptive innovation (Christensen, 1997). According to Flynn (2013), MOOCs describe the varied kinds of changes in an evolving business education environment. The concept bracing MOOCs began in the 1960s; however, this approach to distance education re-ignites because of the digital education age (Flynn, 2013). As posited by Ta'eed (2012), Khan Academy was the first to house the free lectures. The Bill Gates Foundation and Google supported Khan Academy, a non-profit, with substantial backing in 2006. Today Khan Academy has over 3000 short video lectures, which were stated to have over 160 million hits (Severns, 2014; Ta'eed, 2012).

Understanding MOOCs and their relevance is important as MOOCs meaningfully progressed online distance education in past years (Rodriguez, 2012). Standing as an online distance educational model, MOOCs, are supported by colleges and universities; therefore, the need exist for faculty to understand and augment their knowledge regarding MOOCs' past, current and future trends. MOOCs have several prescribed frameworks: cognitive-behaviorist, connectivist social and constructivist (Rodriguez, 2012), connectivism (Pence, 2012), constructivist, connectivist experiential, and social structure, (Koutropoulos et al., 2012). The postulations of these researchers are that MOOCs were formed by technologies

and reside beneath the online distance education environment.

FACULTY DEVELOPMENT IN MOOCs

Through the lens of MOOCs, readers, practitioners, and academicians can postulate the reasons MOOCs emerged on the distance education platform. As educators continue to concentrate on the online distance education environment, comprehending MOOCs is yet another lane in learning for meditation and conjecture. Faculty development with MOOCs has the potential to facilitate networking and permit instructors to converse and discuss concepts and experiences. Professors interested in MOOCs can add value to their repertoire of knowledge by engaging in MOOC mentoring, coaching, and job shadowing programs. Mentorships are associations encompassing a seasoned faculty member who guides faculty with minimal experience or faculty with no experience (Tareef, 2013). Coaching, as given by Rahim and Burrell (2013), is “having an ability to help an employee who has raw talent develop into a star performer”. Job shadowing involves investigating the actions of a professional systematically, and then including the desired actions into one’s work procedures (Leonard, Barton, & Barton, 2013).

Professional development within institutions of higher education remains a significant variable driving excellence of education learners’ academic experiences (Marshall, 2012; Mosley, 2007). Every institution of higher education should establish if, how, and when MOOCs will hold an academic space in their educational lineup. Faculty should comprehend the evolution of MOOCs into and around their institutions. According to Demirci (2014), the syllabus of MOOCs is very similar to other syllabus. Further learning activities are developed to accommodate large audiences. The lessons and activities can be organized as asynchronous and with flex-

ibility (Demirci, 2014). Faculty should look to faculty development programs, mentorships, and coaching to gain additional information regarding MOOCs and their impact.

HOW ARE MOOCs BEING SUPPORTED

Elite institutions of higher education are supporting MOOCs. According to Thrift (2013), an obsession exists with MOOCs because (a) institutions of higher learning are enticed by the promise of profit in educational environments, (b) middle-class aggravation over tuition costs is fueled, (c) economic downturn is propelling countries to seek better priced education that is valued, and (d) MOOCs seem to provide a more efficient mode of education. Pence (2012), provided, the thought remains that partaking in MOOCs may gather meaningful stature. Another advantage of MOOCs provided by Pence (2012) is that MOOCs can produce analytics about education. Analytics can support a drive for operational sustainability. Data regarding MOOCs is found primarily through blog posts (Yong, 2014).

OFFERING MOOCs

Led by Sebastian Thrun, in 2011 Stanford University offered a MOOC. Thrun’s postulation was that eventually participants would graduate with degrees with MOOCs on the transcripts (Krause, 2014). Stanford’s MOOC enrollment was over “160,000 students from 190 different countries” (Flynn, 2013, p. 152). According to Krause (2014), 28,000 completed the courses. The MOOC project expanded. Thrun left Stanford to start Udacity, a for-profit company (Flynn, 2013, Krause, 2014). The goal was to make education a democracy by providing it to learners at no cost (Flynn, 2013). Udacity offers STEM courses, Science, Technology, Engineering, and Math.

Motivated by Thrun, Andrew Ng, and Daphne Koller, two other Stanford faculty members co-founded Coursera, a for profit company (Krause, 2014). Coursera functioned akin to an educational cooperative between Stanford University, University of Pennsylvania, University of Michigan, and Princeton University (Flynn, 2013). According to Krause, Coursera and Stanford, now partners with “33 high caliber universities” (Decker, 2014, p. 7). Coursera courses start frequently and are available in a wide range of topics.

Articulated by Flynn, (2013), \$30 million each in institutional backing, funding of grants, and resources was donated by MIT and Harvard to launch edX, a MOOC. This not-for-profit initiative started with 32 charter members (PR, N, 2014). Harvard is the oldest institution of higher learning in the United States, established in 1636. Harvard’s support of MOOCs is significant. Kolowich (2013a), states that Harvard is very careful with its MOOCs partnerships. Since its beginning, edX has continuously progressed and offers courses on an array of subjects. MIT offers MOOC curricula (Kolowich (2013b).

Initially opposed to MOOCs, universities like Duke University decided against the MOOCs revolution. Disclosed by Kolowich (2013c), the faculty voted the measure down after Duke’s provost, Peter Lange, signed a contract with 2U, a MOOCs group. The *Chronicles of Higher Education* article provided that the faculty’s vote superseded the contract signed by Lange. Now Duke is a part of the MOOCs revolution and advertises MOOCs on its online website. Another institution that initially rejected MOOCs was Amherst College, a liberal arts institution. April 2013, Amherst College’s faculty rejected Harvard’s edX invitation to become a part of the elite association of higher education institutions providing MOOCs (Kolowich, 2013a). During this time, the academe world had mixed views about the MOOCs form of distance education. Today, when viewing Amherst’s web site, MOOCs are now advertised.

MOOCS CRITIQUED

Many elite colleges and universities have supported MOOCs. Some people see MOOCs as innovative and the future of education. Other people understand MOOCs to be all that is wrong with education. What is known is that MOOCs are receiving critiques. According to Rees (2014), MOOCs are akin to students going to the library to check out educational materials and then reading and studying the materials. Some believe that MOOCs will destroy today’s understanding of higher education (Fox, 2013). Others document that the course completion rate for MOOCs is too low (Guzdial, 2013). Questions are surfacing as to whether MOOCs will devalue instructors in the realm of education. The concern of sustaining revenue and not offering too many MOOCs is just another concern. What is understood about MOOCs is that they are perceived as a business model like other educational delivery models.

The MOOCs model was founded on the idea that institutions of higher of learning are the developing segments in line for the high-capacity, low-perimeter data and information-technology treatment after cost review, sales, and the media, as given by Thrift (2013). MOOCs are accessible and accommodate large numbers of learners. MOOCs support lifelong learning. In essence, MOOCs characterizes emerging technology whose educational impact has yet to be fully understood. As shown through Amherst’s and Duke’s later embracing of MOOCs, this form of online distance education will continue to undertake in the practices of higher education.

MOOCS IMPLEMENTATION AND CHANGE

The MOOCs phenomenon has driven an ever-increasing conversation regarding online courses whether in higher education, or business. These developments must be explored from an institutional policy standpoint, focusing on an examina-

tion of the different approaches to MOOCs and e-learning. MOOCs implementation represents change. This change points to (1) curriculum and course design and redesign, (2) a sound e-learning policy as a medium for curriculum development; (3) an emphasis on technology usage; (4) specific policies around licensing; (5) how MOOCs support student advancement; and (6) overall educational enhancement that drives student success.

The change to incorporate MOOCs requires a paradigm shift, a new approach to thinking about online educational processes and technologies. In order for MOOCs to be administered successfully, a top down approach is needed (Burton, 2016). Because people in like organizations will exhibit like behaviors, there must be a change leader to drive communication up and down the communication chain. This leader has to know the key organizational factors: understanding the vision of the implementation, ensuring accountability of key roles for the MOOCs implementation, ensuring the appropriate stakeholders' involvement, determining what skills need to be developed (e.g., developer, staff, students, employees, etc.), ensuring the appropriate metrics, policies and actions, as well as determining how to reinforce behaviors. Initiating the change will require an understanding of the MOOCs implementation range and scope of the project. All leaders and project participants must understand all difficulties and intricacies involved with MOOCs development, and implementations. Timeframe be known for the development and implementation. Most of all, to make the implementation work, all involved must buy-in to the idea.

MOOCs are a disruptive form of education. However; due technology driving learning to the anytime and anyplace environment, the conversation about MOOCs has change. The new conversation need to be about how this form of education will progress leaning institutions and organization toward business process improvement. MOOCs can be implemented as change to support the learning institutions and organizations broader strategic objectives.

OPEN ACCESS LITERATURE

Open access is digital, online, free of charge for everyone with an internet connection, free of most copyright and licensing restrictions (Suber, 2004). Technology has opened many doors and opportunities for the current needs for many academicians, researchers, and practitioners based on the need to have open access availability for literature. The possibility of restricting literature in the future will come at a cost that will be indefinitely become a nuisance for businesses and schools to utilize. MOOC programs of today already are facing the possibility of creating online learning environments that only enhance and filtrate open access literature and learning. Open access has even made it possible for a vast majority of scholars to share theories, research and information such that it can be primarily used in an online database of journals for future reference and research.

Proponents of open access publishing sometimes argue their case on the fairness of providing everyone with access to scholarly material, and by so doing, creating a scientific/academic level-playing field (Nicolas, Huntington, & Jamali, 2007). Open access publishing has become a well known publishing and research style that many scholars, faculty, and practitioners are beginning to position themselves around based on the possibility of other scholars referencing and citing their research and work. This is the ultimate goal of open access literature. With better availability and access to vital research, data can be disseminated to more outside sources to create a better understanding of global research. Therefore, the literature of today needs to be adaptable and accessible for communities and scholars of tomorrow. Creating a validation for open access literature is a primary need for many societies to have based on the utilization of tools in the virtual and traditional classrooms. The tools and styles used are practices of students in virtual learning environments (Bessette & Burton, 2013). The learning environments of the MOOCs are ideally using and utilizing online open access literature and references such that it is readily

available to more people today than ever before. Libraries with traditional literature are becoming outdated as technology for academic advancement is taking place.

The age of the electronic journal has also brought another problem to the library (Chang, 2006). Traditional libraries of today are being more advanced to replace the current physical copy of journals and textbooks and utilizing technology to the max. This adaptation is creating a faster advancement and movement for the retrieval process of literature. More scholars, students, researchers, and practitioners are requiring access 24/7. The increase of the electronic journal and the open access journal are beginning to develop a keen sense of adaption for research to be published and researched at any time in any place. The need for high speed internet access has also become part of the availability and usefulness for online open access literature.

Scholars, faculty, researchers, and practitioners need to coordinate and publish exclusively in all types of scholarly journals. These journals also need to be read and referenced accordingly in

order to successfully develop keen communication between scholars of different disciplines. Without scholastic publishing and referencing of open access work, scholarly research will be under-utilized and problems will persist. Costs of subscriptions for scholastic journals will increase, creating a crisis that is also known as serials crisis. To prevent the “Serials Crisis” situation from becoming worse, research organizations and libraries are starting to support open access publishing (Chang, 2006). Every academic discipline needs to currently outweigh the cost for using and utilizing open access literature based that all research needs to have an open accessible and ideal use based on the needs of scholars for the future.

The utilization of MOOCS into the open access literature will deviate cognitive learning and skill development for students. It is then possible to assume that students will accelerate their learning capabilities to such a level that is currently unmeasured. The need for the open accessibility and developmental change is in the hands of academicians today. MOOC classes will invite,

Figure 1. Screenshot of Directory of Open Access Journals

Table 1. Linux distributions and uses

Linux Distributions	Description and Potential Use	Package
Ubuntu	One of the most popular Linux OS developed to be a complete OS that can be an easily replacement for other comparable OSs.	Debian-based
Edubuntu	OS targeted for grades k-12. Contained in OS are tons of software applications that is useful to those who are education majors.	Debian-based
Damn Small Linux	This OS is designed to as a small OS to be utilized on older hardware. This OS is great for institutions that have old computers and want to revitalize them for use. OS is also great for VMs as DSL requires a low amount of memory.	Knoppix-based
BackTrack	OS based on Ubuntu for digital forensics and penetration testing. Great tool for students majoring in technology fields. As cyber security is becoming a hot topic around the world this tool provides students the ability to learn from over thirty software applications that aid in penetration testing and more.	Debian-based
Fedora	This OS is supported by the Fedora Project and sponsored by Red Hat. This OS provides a great resource for learning Red Hat Enterprise Language (RHEL). As there are thousands of jobs requiring expertise specifically with Red Hat this OS is a great tool to prepare students for employment in IT. Fedora has over six Fedora Spins such as Design-suite, Scientific-KDE, Robotics, Electronic-lab, Games, and more.	RPM-based
Kali	An advanced forensics and penetration testing distribution that is the successor of BackTrack.	Debian-based
Elementary	OS is based on Ubuntu and showcases the Pantheon desktop. This OS is focused on usability, and design aesthetics. The desktop environment has been compared to Mac OS. This desktop origins from being an Ubuntu desktop theme.	Debian-based
CentOS	This OS derived entirely from RHEL. The source code is developed from Red Hat which allows a student to learn RHEL with a small number of differences. CentOS can be used for teaching IT students on how to setup, administer, and secure a server.	RPM-based
Ubuntu Studio	This OS is derived from Ubuntu. This OS is developed specifically for multimedia production such as audio, video, and graphics. Departments for multimedia could use this OS for multimedia instruction and the development of projects. As many of the tools for multimedia production are expensive this alleviates large license costs for institutions.	Debian-based
Lubuntu	OS is based on Ubuntu and uses the LXDE desktop environment. It replaces Ubuntu's Unity shell and GNOME desktop.	Debian-based

enhance, and protect the vital means of academic learning through learning techniques as part of program changes and alterations. Open access literature is needed for MOOC system improvements as well as academic and career changes nationwide. In the figure below is a screenshot of the Directory of Open Access Journals (DOAJ) which is of one of the most popular sites for open access refereed works.

STEM NEEDS FOR MOOCS

As STEM is continues to play a critical role in America, Linux could provide the ability an affordable large scale deployment. Even more important is the environment where individuals can practice skillsets and techniques learned from the classroom. Thus, Linux provides the ability for students to perform low level code analysis. In developing the class environments with cost in consideration Linux allows for this to be done with removing costly barriers with the exception of hardware. The barriers are proprietary software licenses, and software that operates on a particular

Figure 2. Elementary Linux in a VM

hardware configuration. The associated software licensing allows for applications to be used freely in MOOCs for enhancing the overall experience.

The addition of Virtual Machines (VM) in MOOCs enhance the overall courseroom experience. VMs can be loaded to the MOOC site which mimic the instructor's teaching environment for a particular course [See Figure 2]. The course tools such as programming environments, networking tools, offensive security applications, and more can already be included in the VM. Additionally, this environment can be exported to an ISO image file so that as this file format will work with multiple hypervisors.

SOFTWARE LICENSING

When considering software licensing it is essential to understand the license agreements for the applications that are used within the MOOC (Dawson, Leonard, & Rahim, 2015). This will allow for the use or redistribution of software. The use of OSS can greatly enhance the STEM environment (Dawson, Al Saeed, Wright, & Onyegbula, 2014).

GNU GPL v3

After a review of the terms and conditions provided by this license it appears to be more comprehensive in its requirements for use of the licensed software. It contains several more terms and appears to contain many more prohibitions than the previous version of the license terms contained. It contains the requirement to include appropriate notices for distribution of the code. It also contains specific prohibitions regarding restriction on the subsequent use of the code, including modified versions, by downstream users (Kumar, 2006).

GNU GPL v2

After review of the terms and conditions of this license, this version's license does not appear to have as many requirements and certainly is not as long as the newest version of this software's license appears to be. While considerably shorter than the subsequent version's license, this license does still maintain and include the requirement that appropriate notices accompany the distribution of the code (Kumar, 2006).

LGPLv3

After review of the terms and conditions of this license, this version's license does not appear to have as many requirements as either of the licenses under the GNUGPLv3 or v2, but it does maintain several requirements for compliance. Of note, is this license includes an exception to the GNUGPL license, namely that the work produced under this license may be reproduced without compliance with Section 3 of the GNUGPL, which relates to Protecting Users' Legal Rights from Anti-Circumvention Law.

LGPL v2

After review of the terms and conditions of this license, this version's license appears to somewhat longer than the terms and conditions of the subsequent version's license, but it appears to be closer to the GNUGPLv2's license terms than the LGPLv3's terms and conditions, and noticeably does not include the exception to the GNUGPL license as is contained in the subsequent version of this license.

LLGPL

After review of the Lisp Lesser General Public License (LLGPL), this version's license is like the LGPL but with a prequel. This prequel defines the effect in terms more typically used in Lisp programs. This license is grounded in the C programming language as the license specifically calls out functions not present in other languages that are not traditionally compiled (Greenbaum, 2013).

Apache 2.0

The previous Apache licenses were based on the GPL v2 however the Apache License v2 permits code that is covers to be subsumed into closed source projects (Rosen, 2015). It also explicitly

grants patent right where necessary to modify, operate, and distribute the software.

MIT License

The MT license provides permission, free of charge, to any individual obtain a copy of the software and associated documentation. Additionally, it (Rosen, 2015). Also provided without limitation is the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the software (Rosen, 2015).

Creative Commons

After review of the terms and conditions of this license, it appears that this license is very similar to that of Modified BSD. It is interesting of note that the license begins by indicating that the company is not a law firm. Additionally, this license appears to include a waiver of copyrights and related rights, and a fall-back in the event that the waiver is invalidated, which appears to be based upon the purpose of promoting the overall ideal of free culture. In addition this license includes a limitation to make sure that neither patent or trademark rights are being waived by this license.

Artistic License 2.0

After review of the terms and conditions of this license, this license appears to be very similar to that at issue in the Jacobsen case discussed above. Moreover, it appears that this license makes clear that the copyright holder intends to retain some creative control over the copyrighted work overall, while still trying to ensure that the copyrighted material remains as open and available to others as possible under the circumstances.

Modified BSD

After review of the terms and conditions of this license, these terms and conditions appear to be the shortest list of terms and conditions of all of

Figure 3. System Engineering Virtual Test

the licenses reviewed in this paper. Additionally this license appears to allow reproduction and modification of the copyrighted material provided certain conditions are met, which if subject to legal challenge, a court might construe as being subject to only protection as a contract, at best, and a bare license at worst. Moreover, based upon the legal authorities cited in this paper, it may be unclear whether this license may provide sufficient copyright protection.

Clear BSD License

After review of the terms and conditions of this license, this license appears to be very similar to the Modified BSD License, in that it is very short, and appears to allow reproduction only if certain conditions are met. This license does make clear that no patent rights are granted by this license.

VIRTUAL WORLDS

Virtual worlds can provide a platform to teach the labs in an environment that is dynamic and takes advantage of ubiquitous learning (Davis,

Dawson, & Omar, 2016; Dawson & Al Saeed, 2012). Access to a MOOC could occur in a manner that a student performs an engineering lab design in the virtual world environment. This would allow the individuals to have a low fidelity lab in which the activities provided in the MOOC can be done in an environment that allows for synchronous or asynchronous participation. The MOOC environment could be enhanced with the use of virtual environments with the use of virtual laboratories, virtual museums, augmented reality, collaborative e-learning, Neto, de Souza, & Gomes, 2016).

CONCLUSION

Despite the fact that many innovations in the field of educational technology have existed throughout the decades, undoubtedly the most conspicuous public conversations in mainstream media are pointed to the phenomenon, massive open online courses (MOOCs). Pappano (2012), in her New York Times November 2012 article branded the year 2012 as the “Year of the MOOCs”. This labeling help to propel MOOCs into being a significant educational technological catchphrase.

Conceptually, MOOCs appeared to be the utmost in learning in the online space; however, glitches appeared. These glitches include but are not limited to underwhelming involvement, lower than expected completion rates, and imbalanced content significance according to Marrapodi, Shimkus, and Onisk (2016). Notwithstanding the rising accessibility, attraction, and probability of MOOCs, their economic justification and their academic value required more exploration, and particularly the technological aspects.

FUTURE RESEARCH DIRECTIONS

More research is needed regarding MOOCs and quality of development, MOOCs and STEM needs, as software licensing. The data shows that the instructional quality of MOOCs varies. With this said instructional principals must be revisited to determine a best practice. Data needs to define the top principles of learning for MOOCs, and the specific types of learning environments. Some data exist about MOOCs in STEM education; however, more is needed. A key point of focus will be having the appropriate mix of academic information to learning exercises (e.g., videos, assignments, and activities). The key point is to make learning stick. Finally, when determining the type of MOOC course to develop, the development team must have a better understanding of the type of licenses required for MOOCs. It is important to know that key obstacle in terms of licenses are proprietary software licenses, as well as software that operates on a distinct hardware configuration. The associated software licensing permits the applications to be used freely in MOOCs for enhancing the overall experience

MOOCs encompass a host of different types of courses. These types of courses allow for global delivery. Delivery approached will continue to vary; however, will need to be studied and concentrated as to the needs of different student populations. Technology is important; thus, due to ubiquitous technological advancement,

software licensing will have to be consistently reviewed. MOOCs can prove useful as a new phenomenon of course delivery for students, faculty, and administrators to use. To effectively do this one must maximize the technical use OSS, open source technologies, and open access literature while minimizing the overall associated license costs. The use of virtual worlds with MOOCs would provide students an environment that allows student to be fully immersed in required technology labs (Calongne, 2008).

KEY TERMS AND DEFINITIONS

GNU Public License: A widely used free software license that is managed under the GNU Not Linux Project (Stallman, 1991).

Linux: An open source version of the UNIX OS (Perens, 1999).

MOOC: An online course with the option of free and open registration, publicly shared curriculum, and open ended outcomes (McAuley, Stewart, Siemens, & Cormier, 2010).

Open Source Software: Software that allows the original source code to be free available which may be freely redistributed or modified (Perens, 1999).

Software License: Legal instrument for governing the use or redistribution of software (Dawson, Leonard, & Rahim, 2015).

Open Source Software Virtual Learning Environment (OSS–VLEs) in Library Science Schools

Rosy Jan

University of Kashmir, India

INTRODUCTION

The cost of higher education with the attrition of formal learning and the rise and evolution of informal learning presents a unique challenge to academic institutions. Students can no longer afford the cost of textbooks, and the use and embracement of proprietary software limits the freedom of knowledge exchange. The situation is further stimulated by considerably changed attitude and skills of students in IT over the last few years. The transformation of web from static to dynamic has changed the perception of the younger generation towards information presentation and availability. The younger generation now expect to be in ‘constant connectivity’ with friends and family taking the benefit of participatory and interactive nature of the web. They increasingly expect technology to have a significant role in their learning also. Learning styles are growing fast as the technology grows in the world. New techniques are forthcoming within the higher education system to get the better student’s presentation, tutors philosophy and the institution enlargement. Information and Communication Technology innovates the new technologies for conversing the information and knowledge to have a different transform for teachers to teach and for students to learn Ruíz, Martínez & López (2016). So, need emerged to rethink how we teach and how we use learning technologies and how education is delivered. In response to this changing environment, e-learning is being implemented more and more frequently in higher education, creating new and exciting opportunities for both educational institutions and

students. E-learning means “instructional content or learning experience delivered or enabled by electronic technologies” (Ong, Lai & Wang, 2004). Which more recently, include mobile and wireless learning applications. E-learning is increasingly adopted in the workplace for supporting professional development and continuing education; however, in higher education, the use of e-learning is predominantly used as a tool support teaching (King & Boyatt, 2015).

The variations in the configuration of e-learning offerings can be described through a number of attributes. One of such attributes is the use of VLEs. A Virtual Learning Environment (VLE) is a software system designed to facilitate teachers in the management of educational courses. The system can often track the learners’ progress, which can be monitored by both teachers and learners. While often thought as primarily tools for distance education, they are most often used to supplement the face-to-face, classroom as well as blended learning. VLEs are defined as “computer-based environments that are relatively open systems, allowing interactions and knowledge sharing with other participants and instructors” and providing access to a wide range of resources (Wilson, 2006). “The Joint Information Systems Committee (JISC) considers a Virtual Learning Environment (VLE) an online environment in which learners and tutors participate in “on-line” interactions of various kinds” (JISC, 2000). Besides many more names VLEs are also referred as online learning environments, learning management systems or collaborative learning software (Britain & Liber, 2000). The first systems that fitted the criteria of

DOI: 10.4018/978-1-5225-2255-3.ch688

VLEs as we know them now started to emerge between 1995 and 1997 (Stiles, 2007). VLE is a boxed system that mediates between teacher(s) and student(s). They have a consistent and customizable interface and a clear navigational structure (Stiles, 2007). Access to the environment is often ubiquitous and supports anywhere learning with the support of internet connection (Jacobsen & Kremer, 2000).

The value of a VLE is to fully bring out the characteristics of both “Learning Any Where” and “Learning Any Time,” and the purpose of a VLE is to emphasize and diffuse thinking models, diverse viewpoints, independent thinking, etc. (Chou & Liu, 2005). Plethora of research conducted on VLEs has reported positive impacts from various contexts. They can; increase enthusiasm and confidence, improved readiness to learn, promote reflection, accommodate the needs of students and broadly reported improved course assessment performance (Means, Toyama, Murphy, Bakia and Jones, 2009). More recently, the research targets at using on Web 3.0 – based personalisation of learning objects (LOs) while learning in virtual learning environments (Kurilovas, Kubilinskiene & Dagiene, 2014).

Keeping in view the benefits, the work has been initiated to review concept, features and issues of virtual learning environments. Some of the most used OSS VLEs are discussed. Further it determines the suitability of a VLE for higher education. The chapter also explore and identify the recent contributions to the concept by analyzing ongoing virtual learning initiatives and projects by different organizations and information centres to stimulate future Research and development trend in the field.”

BACKGROUND

Technologies are affecting almost all facets of life be it business, entertainment or social activity. Commentators and futurists suggest that there are profound implications for education as well.

They argue that because the “Net Generation” of learners is so engrossed in a networked world of digital technology, they behave differently, have different social characteristics, different ways of using and making sense of information, different ways of learning, and different expectations about life and learning. So, need emerged to rethink how we teach and use learning technologies and how education is delivered.

In response to this changing environment, one of the means of education that has been propagated with internet revolution is e-learning. e-learning is being implemented more and more frequently in higher education, creating new and exciting opportunities for both educational institutions and students. E-learning means “instructional content or learning experience delivered or enabled by electronic technologies” (Ong, Lai & Wang, 2004). Naresh and Reddy (2015) identified the key factors of successful implementation of e-learning in both developing and developed countries and concluded that financial support from governments, students’ motivation and well trained tutors are important for such implication. In addition, user perception and readiness also play an important role in e-learning effectiveness. The barriers faced to a larger extent by developing countries than developed ones are as follows: lack of infrastructure, trained instructors, lack of financial support, government policies and less student readiness. Developed countries, on the other hand, have a strong infrastructure and face the following challenges: student engagement, student motivation, and high student drop out ratio. It has been observed that the variations in the configuration of e-learning offerings can be described through a number of attributes. One of such attributes is the use of VLEs.

A VLE is a web-based communications platform that allows students, without limitation of time and place, to access different learning tools, such as program information, course content, teacher assistance, discussion boards, document sharing systems, and learning resources Martins and Kellermanns (2004). VLEs electronically

support training and development in higher educational and vocational training settings. These are frequently used and preferred over the traditional systems keeping in view the benefits like ubiquity, timeliness, efficiency, individuality and learning task orientation. They do so by offering a repository for course documents, discussion forums, chat boxes, mass communication options, etcetera.

Within the overwhelming amount of technology acceptance studies Sun and Zhang (2006). The number of those studying the acceptance and use of VLEs is small but growing (Martins and Kellermanns 2004; Ngai, Poon & Chan, n. d.; Ong et al, 2004; Pituch & Lee, 2006 & Selim, 2003). VLEs are rapidly becoming an integral part of the teaching and learning process (Pituch & Lee, 2006). Ahmed and Morley (2010) qualitative and quantitative explored how a Virtual Learning Environment (VLE) can be supported in a Higher Education setting. Findings revealed that holistic support strategies were capable of targeting larger groups of teachers effectively via staff development workshops and strategies. Study by Mimirinis and Bhattacharya (2007) presents the results of a case study which explore the relationship between approaches to learning and studying, and perceptions of use of a VLE in a Higher Education taught module. Further the study investigates the requirements for appropriate design of VLEs. Recommendations are aiming to highlight the importance of specific elements in the design and delivery of online courses through VLEs. Graham, Woodfield & Harrison (2013) observed that there has been rapid growth in blended learning implementation and research focused on course-level issues such as improved learning outcomes, but very limited research focused on institutional policy and adoption issues.

Comparisons of traditional classroom learning and studying with a VLE have been carried out by Piccoli, Ahmad and Ives (2001), Kekkonen-Moneta and Moneta (2001), Marandi and Luik (2003), Zhang et al. (2004) and McDonald et al. (2004). VLEs have advantages compared with traditional teaching. When different teachers lecture

on the same topic, no two lectures are ever exactly the same. Furthermore, the same teacher hardly ever repeats the same lecture in exactly the same form or with exactly the same content (Walker & Harrington, 2004). Lecturers can de-motivate students with their routines. On the other hand, VLEs are a flexible way of teaching (Walker & Harrington, 2004) because VLEs can be used at the most convenient time (Clarke, 2001). The learners learn beyond the timetable routines and guidelines, and therefore chances of missing a lecture is rare (Walker & Harrington, 2004). Lee et al. (2002) found in their study that positive attitudes towards using computers were the key factor in the VLE's success. Students' positive relationship to computers helps also the learning process (Lee et al., 2002). Costello (2014) highlighted that Virtual learning environments (VLEs), such as Moodle, have become an integral part of the complex infrastructure of higher education systems throughout the world. However, Babic (2012) argued that both educational practice and scientific research indicate that teachers' insufficient use of VLEs in higher education teaching still represents a problem. It would not be honest to claim that virtual learning environments will improve the quality of education or reduce the costs of educational systems. These environments have some potential effects. However, the past tells us that it is very difficult to set up the conditions that turn potential into actual effects. Nonetheless, even if there were no proof of superiority in terms of learning outcomes, the evolution would not stop. The issue is not to prove the effects but to understand them.

Coppola (2005) highlighted and focused the e-learning platforms (both LMS and LCMS). Author concluded that the platforms currently available are based on either proprietary e-learning software (PES) or open source e-learning software (OSS). Further it was observed that OSS usage in implementing e-learning systems is more emphasized due to the challenges faced when implementing the PES. Open source software offers the potential to reduce the cost of the software while providing

the universities greater control over its destiny. Elimination or reduction of license leaves more budgets available to invest in adapting and managing the software; offers reliability, performance and security over proprietary software due to the availability of the source code, which allows vulnerabilities to be identified and resolved by third parties and it is easy to customize. Some of the widely used open-source e-learning software programs are the Claroline and Moodle. Littlejohn et al (2006) found that with the merger of Blackboard and WebCT, the selection of the open source system Moodle is an increasingly attractive alternative for many institutions. The Open University (OU) recently choose Moodle as a core component of its virtual learning environment after an extensive requirement-gathering process and evaluations of commercial and open source products demonstrate the way of using the Moodle in the education process at the Gaia Vocational School (GVS). The platform was characterized and promoted among the School members of GVS. The impact of this new platform (e-Courses) on the learning institution activities was evaluated through an online questionnaire, which showed high satisfaction levels with e-Courses. Thus, regarded MOODLE an excellent example of learning management system (Syed, 2009). Report from the Croy, Smelser and McAlpin (2009) describes the results of an evaluative comparison of the Moodle Learning Management System with the Blackboard system. Recommends that the University of North Carolina adopt Moodle as its sole Learning Management System; and Outlines the consequences of doing so in conjunction with a plan for making the transition from Blackboard to Moodle. Hodhod et al. (2010a) found that current market place for VLEs in HEIs is dominated by two products Blackboard and WebCT, each offering a variety of tools and functionality. Many other products are available and in wide use such as First-Class and LearnWise. More recently the advent of open source has offered the academic community Moodle. This VLE is fast superseding the proprietary products as being the most popular

and easy to use system of choice apart from many licensed VLEs like BlackBoard, desire2learn, CyberExtension or It's Learning; there are few open source VLEs as well in the market. Adoption to open source VLE is very much dependent on requirements of the organizations. Famous open source VLEs are Bodington & Moodle. A comparison between the available free VLEs Claroline, Moodle and Atutor by Hodhod et al (2010b) to assure that Moodle is really the suitable choice and it holds the suitable features for a good learning environment. White paper by Luzet (2010) provides brief overview of the usability of the main features of Moodle and Fronter. The results of this work reveal that Fronter wins out from a usability perspective in its simplicity: it offers fewer options and is therefore easier to grasp for a novice user. On the other hand, Moodle's help system scores highly for its comprehensive and content-specific help documentation. Further Moodle is more flexible and scalable which makes it popular as the educational institutions become more demanding in their needs. A comparative study of Moodle with other e-learning systems by Kumar, Gankotiya & Dutta (2011) focused on the Moodle Architecture and presents some authentication plug-in that Moodle supports. LMS Moodle has been adopted by many people and organizations around the world because it offers a tightly integrated set of tools said to be designed from a social constructive perspective. Moodle has been developed under the general public license and many of its components were developed without a specific design documentation including its security services. Ajlan (n. d.) in a book chapter study, analyze, and explore the right decision when choosing a suitable VLE platform to meet the requirements of Qassim University. It focused on a comparison between Moodle and other VLE systems, and is based on two kinds of comparison. This study has proved that the best platforms are Moodle and Sakai, which have missed just two out of forty features. Other than the comparative studies recent studies focused on the development process different

experiences and perspectives of the staff involved. Study by Buus (2016) highlighted the development process and some of the didactic considerations undertaken for the implementation of VLE. The evaluations undertaken during the process was presented, along with the results collected in the use of Moodle to highlight the educational changes. While as Sinclair & Aho (2016) presents initial, qualitative research aimed at understanding how Moodle is being used and the different experiences and perspectives of the staff involved. To generate themes and areas of interest for future investigation the paper uses interview data from two “expert witnesses” having a deep understanding of how the platform is used. Emergent themes include: divergence between confident and basic users; the spread of usage within an academic community; lack of progression to innovative teaching methods.

VLE IN LIS SCHOOLS

The field of library and information science is presently passing through a phase of rapid changes. This situation demands an educational system of continuing or life-long learning for new technologies, methods and service procedures. The augmentation of traditional classroom activities with electronic learning objects along with the rise of the free and open source software based course management systems is changing the way faculty and students access, create and use learning objects, information and knowledge FERL (2005). It is providing new opportunities for libraries to design and to disseminate new services. Library schools are also investigating the use of VLE in imparting traditional classroom based courses as well focused and continuing education and/or training programmes for LIS professionals. In fact, the relationship between VLE and LIS profession may be viewed from two angles – application of LIS services in virtual learning environment and use of VLE in design & delivery of traditional as well as focused courseware. OCLC in its white

paper McLean (2003) prescribes following library supported services for a typical VLE: Consecutive display and integration of a variety of information windows as part of a learning activity, Aggregation of access to content in any given learning context, Provision of bibliographic tools, Integration of plagiarism software into course management systems, Integration of library resources in course management systems, Customization of portal facilities for storing personal preferences. Paper by (Singh & Devi, 2009) highlighted VLE, Virtual Community, Characteristic features, objectives, Issues, Essentialities, Choice of content, etc. LIS Education in VLE emphasizes on the American Experience, IGNOU initiatives in India concluded that Indian LIS Schools should adopt virtual learning system. However, paper by Mukhopadhyay (2006) concentrates on use of VLE in managing LIS courseware. The author has experimented the design of vidyaOnline, the prototype web-based modular and interactive learning system, aimed to produce a Virtual Learning Environment (VLE) for library and information science courses as well as for other distance and traditional courses of Vidyasagar University. The structure of Vidya-Online extends support for all three forms of VLE – web-based training, supported online learning and informal e learning. Chowdhury and Chowdhury (2006) describe the findings of the initial phase of the eLLIS that aims to study the current practices and support for e-learning available in the Library and Information Science departments in UK. The paper provides a snapshot of the current practices, highlighting the most interesting ones, of e-learning supports provided by the LIS departments and the libraries of the corresponding universities. This paper shows that all the LIS departments and the corresponding university libraries provide some supports for e-learning, though the nature of these support services varies significantly. Most LIS departments in UK currently offer a blended learning environment. Islam, Chowdhury and Islam (2009) examine the LIS education in e-learning environment and its implications in other areas. This study also gives

an overview of e-learning education systems in Bangladesh and finds out problems of e-learning in LIS educations in Bangladesh. The findings reveal that Bangladesh needs a proposal to acquaint with this system. It provides a proposal to apply distance and e-learning modes adopted by different LIS institutions in Bangladesh making some recommendations for implementing the proposal. Paper by Lihitkar (2010) attempts to provide a conceptual idea to build-up a prototype model for VLE@DLISc,RTMNU in ICT environment by integrating the two software i.e. Moodle and GSDL. Paper by Arora and Lihitkar (2015) endeavours to discuss the need of VLE in the present LIS education, its pros and cons and also some issues that one will face while implementing it for university, college, or any educational institute. While as Qutab, Shafi-Ullah, Safdar & Khan (2016) explores the use of Virtual Learning Environment tools by professional library associations for career development, collaboration, networking, and building communities across the globe. The paper further emphasised that Continuing Professional Development is the dire obligation of the practising library and information professional in the challenging information society, ever-changing user needs, and advancing support tools. The national and international library associations carry the responsibility of the CPD for the librarians. Traditional face-to-face training, discussions and conferences are supplementary with eLearning platforms, making acquisition of knowledge easy, accessible, economical and thus possible across the geographical limits for career advancement. While as Watkins & Sheu (2016) presented the concept of open knowledge diffusion and the effects of social inertia in preserving constrained learning environments. Authors identified and explained Open Knowledge Diffusion Tools (OKDT) such as Open Educational Resources (OER), Open Textbooks (OT), Massive Open Online Course (MOOC), and Free and Open Source Software (FOSS).

FUTURE RESEARCH DIRECTIONS

The future of learning is outside the traditional campus and classroom. There are profound advances and changes in technology resulting in rapid and unparalleled changes in learning and teaching. The default access points will be mobile phones, laptops and tablets keeping in view the plethora of new devices and APIs as well as super-fast internet speeds available around the world. The future will turn and twist the whole gamut of educational system. Thus, the changes and disruptions to traditional form of university teaching in general and teaching in LIS School in particular will be wide and profound. The LIS schools that mainly rely on disseminating information in traditional classrooms will have fewer resources to such an evolution and therefore will be pressured to bring changes. So, the only way to deal with that will be by investing in blended learning, using the flipped classroom model. The future lies in the use of Open Knowledge Diffusion Tools and the potential of Three-Dimensional Multi-User Virtual Environments (3-D MUVES) such as Second Life (SL) in the service of learning.

That leads towards infinite imaginative educational possibilities. The future lies in extending classrooms practice, curriculum enhancement, engagement of students, teachers and administrators to support learning, promote collective creativity and shared leadership and unite learning groups with shared values, vision and practices in a global perspective.

CONCLUSION

Open Knowledge Diffusion Tools, MUVES and other latest leaning technologies of the future will offer a very different set of features and tools. The recent merger and ongoing development of various VLEs like SAKAI and other open source products, which offer the promise of

easily shared learning tools, and new techniques such as AJAX, will drive the change process. Eventually, a more responsive set of learning tools will be a demand of upcoming generation of students. Just as they are quickly moving beyond the traditional institutional environment to create their own virtual social realms, they may one day create and utilize their own learning tools and communities. Of course, institutions will always hold the upper hand in these developments as they maintain the formal credentials students require for future careers. But this exercise of power is an illusion in a rapidly changing society and we want to engage our students through experiences that are both empowering and transformative. Doing this will require that we rethink about our teaching model, and grasp the reality that the underlying paradigms are, indeed, changing faster than we think.

KEY TERMS AND DEFINITIONS

E-Learning: Education via the Internet, network, or standalone computer. It is essentially the network-enabled transfer of skills and knowledge. E-learning applications and processes include Web-based learning, computer-based learning, virtual classrooms and digital collaboration.

Massive Open Online Course (MOOCs): An online course aimed at unlimited participation and open access via the web. In addition to traditional course materials such as filmed lectures, readings, and problem sets, many MOOCs provide interactive user forums to support community interactions among students, professors, and teaching assistants (TAs). MOOCs are a recent and widely researched development in distance education which were first introduced in 2008 and emerged as a popular mode of learning in 2012.

Moodle: Moodle is free and open-source software learning management system written in PHP and distributed under the GNU General Public License. Developed on pedagogical principles. It is used for blended learning, distance education, flipped classroom and other e-learning projects in schools, universities, workplaces and other sectors.

Open Source Software: Software with source code that anyone can inspect, modify, and enhance.

Virtual Learning Environment (VLEs): A system for delivering learning materials to students via the web. These systems include assessment, student tracking and collaboration and communication tools.

Teacher Presence

Caroline M. Crawford

University of Houston – Clear Lake, USA

INTRODUCTION

The impact of the online instructor, whom one may label an instructional facilitator, within distributed learning environments has become a topic of interest over the previous decades. The impact of the instructor is not only clear within a traditional face-to-face and blended learning environment, but is also vitally important within a distributed learning environments. Although the impact of the instructor upon the learner's experience and subject matter understanding has not been fully understood, the needs revolving around instructor presence within distributed learning environments are not merely motivational in nature. Instead, instructor presence also serves as a facilitative guide, self-regulatory maven, cognitive load support system, and the mentor-focused instructional effort towards not merely cognitive understanding but also towards higher order thinking skills and associated subject matter engagement.

BACKGROUND

Within the bounds of a discussion related to the concept of teacher presence within an instructional environment, there has been intriguing work revolving around the concept of the teacher's impact upon the instructional environment for decades. Of interest is the distinct engagement within this subject during the 1980s and again arising in the later 1990s due to the introduction of instructional technologies and distributed learning environments into the instructional environment. A discussion revolving around understandings related to teacher presence and subsequent impacts upon the instructional environment are addressed. Se-

DOI: 10.4018/978-1-5225-2255-3.ch689

cifically, focusing upon the subjects of discourse, reflective practices, and motivational needs of the learner.

Towards supporting this understanding, Laidyschewsky (2013) engaged in the impact of the instructor's presence upon the learner satisfaction, and is in strong company with current instructor presence engagement in online courses (Bowers & Kumar, 2015; Hodges & Cowan, 2012; Lowenthal, 2009; Sheridan & Kelly, 2010) and associated multimedia-based efforts towards the suggestion of instructor presence (Young, Hicks, Villa-Lobos & Franklin, 2014), as well as professional associations' efforts towards supporting the engagement of teachers within online learning environments (NEA, n. d.). The teacher presence efforts and associated student perceptions surrounding teacher presence are currently intriguing and worthy of further consideration.

Discourse

The concept of discourse within an instructional event is of significant interest. The importance of discourse is not only due to the inherent social engagement of the learner within an instructional environment, but also upon the understanding of the teacher's instructional and facilitative impact upon the learner. As well, the communal understandings revolving around practices within the institutions that undergird the instructional efforts directly impact the concept of discourse within the instructional environment.

Social Discourse: Words We Use

The instructional process is a socially framed effort, no matter whether learning occurs within a

face to face instructional environment, a blended learning approach, a distributed learning approach or even a mobile instructional environment. The ways that people learn new knowledge and information is framed through a socially mediated environment. For this reason, an introductory discussion that focuses upon the words that are implemented throughout the social discourse effort are vitally important. An initial point of interest is Wittgenstein's (1961) research that engaged in an understanding about the words that people implement within an instructional environment, not only to frame an understanding of the knowledge but also perceptions revolving around the nuanced understandings of the knowledge. The word choices of the instructors, the word choices of the learners and perceptions of understanding as framed through these word choices directly impact the learning environment's social discourse. Word choices reflect one's understanding of the knowledge, as well as the nuanced subject matter understandings. The simplistic shift of the instructor's word choice, from "student" to "learner colleague" or merely "colleague", directly impacts the perception of the learners within the instructional environment. One example is offered by a master's student towards the end of a semester-long course, when stated "I also appreciate that you view us as colleagues and not just students. Thank You!!" (personal communication, 27 April 2016), suggesting that the labels and terminology articulated by the instructor not only reflects upon the community endeavor and style of engagement but also upon the perception of the instructor's presence within the course environment.

Further, one may consider Vygotsky's (1933/1966, 1935, 1981) work as pertains to the ways that people understand the knowledge within the instructional environment as conceptually framed through social understandings. Ways that instructors and learners talk about the knowledge within an instructional environment is important, just as the socially relevant engagement with the subject matter more fully frames the learner's understandings of the information through

knowledge checks and corrections in developing understandings of the information. Following on this thought process is Cherryholmes' (1988) structural understanding of discourse as it is bound by the conception of time and place. Meaning, the instructionally relevant discourse that occurs within a socially relevant and engaged environment is supported by the short-term memory understandings that are bound by the instructor's and collegial learner's efforts. Discourse is inherently framed through a cognitively conceptual engagement within a specific time and place cognitive understanding. The usage of the information learned falls within a specific locale and a specific point in time; as such, understanding this information is also bound by the developmental appropriateness of the learner working with this information, as well as the engagement of the instructor within the social discourse that further frames the learner's understanding of the information. Of interest is the shift from social discourse towards patterns of behavior, distinctly framed within the practices of the instructional institutions; although each is directly relevant and supports the other, these are distinctly separate events and practices.

Patterns of Behavior and Practices of Institutions

The language of the instructional environment and the language choices of the instructor directly impact the learner within any type of instructional environment. Not only does the type of discourse occurring reflect differentiated patterns of behavior directly related to the subject matter understanding within the field. However, the instructor's discourse style and discourse engagement with the learners may directly impact the learner's understanding of the subject matter as well as the learner's success associated with knowledge attainment and holistic engagement with the subject matter (Smith & Zantiotis, 1988). The terms implemented by the instructor, the ways through which the chosen texts represent the information and even the multimedia products

that digitally represent the subject matter integrate styles of discourse and subject matter framing of thought processes that can support the learner. On the other hand, the disengagement of the learner from understanding or even motivation towards learning more about the subject matter presented is a realistic concern. The instructor's curricular choices, the instructor's instructional design efforts, and the instructor's style of discourse and engagement support between the subject matter and the learner each leads towards a recognition of the importance of the teacher throughout the instructional process. The teacher is present throughout each instructional choice, analyzing the appropriateness of the subject matter presented to the learner, framing the learner's understanding of the knowledge base and subsequent working with the new information in different cognitively creative manners. As such, all levels of engagement revolve around the teacher presence throughout the subject matter discourse efforts.

Reflective Practices

During the latter half of the last century, a developing interest in the teacher's ability to reflect upon their instructional abilities and engagement support between the subject matter and the learner's cognitive understandings became a prime area of recognition within a constructivist understanding of learning and engagement. As such, Cruikshank's Reflective Teaching Model (1988), Schon's Reflection in Action (1983, 1987) and Zeichner's Three Levels of Reflection (1981, 1983; Zeichner & Liston, 1987) were important models and theories representing the shifting understandings of teacher presence within the instructional environment, and the importance revolving around the instructor's professional analytical efforts as regards the instructional process.

Cruikshank's Reflective Teaching Model

Cruikshank's recognition of the importance of reflective practices within the teaching profes-

sion developed into a Reflective Teaching Model (1988) that purported to support the continual professional development of the instructor through continuously reflecting upon the instructional practices inherent within the learning environment. The ability of an instructor to continuously and critically analyze one's own instructional practices and instructional impact upon the learners and the learning environment were inherent needs. The ability of an instructor to analyze one's own effectiveness within an instructional environment, not only within the holistic instructional environment but also within a learner-by-learner impact analysis, are suggested as being reflective analytical efforts that suggest an integrated understanding of one's own instructional impact beyond themselves as teacher individuals and taking into account the instructional community impact.

Schon's Reflection in Action

Schon's Reflection in Action (1983, 1987) work is less interested in a strictly framed reflective analytical engagement on the part of the course instructor, and more fully engages the instructor in a holistic understanding of instructional impact. As suggested by Schon's statement wherein the focus should be upon the "competency and artistry already embedded in skillful practice" (1987, p. xi), the inherent professionalism of the instructor and the subsequent instructional presence throughout the learning process is more fully acknowledged by Schon's work.

Also, recognized within Schon's work are three primary areas of focus: tacit knowledge; knowing in action; and, reflection in action (1987). The concept of tacit knowledge is the reflection of the instructor's instructional presence through the experience of the professional instructor's ability to engage the learner with the subject matter. Again, as suggested by Schon (1987), "We reveal it by our spontaneous, skillful application of the performance; and we are characteristically unable to make it verbally explicit" (p. 25), suggesting the actively engaged instructor's presence with the

knowledge and “knowing” within the instructional environment, suggested as being actively vibrant and framed within a circumstance or condition that is naturally occurring within an instructional environment. The final consideration is the ability of an instructor to be reflective in instructional action and presence; specifically, this is the ability of an instructor to unconsciously and consciously reflect as one is progressing through an instructional event or an instructional design effort, while at the same time being able to recognize the verbal and nonverbal cues of the learners as pertains to the level of understanding and engagement with the subject matter. An example of this effort is towards an instructor’s ability to showcase their analytical thought process, either through the word processed communicative style, a video-based presentation of an analytical reflection, or perhaps a synchronous video conference event wherein the learners have the cognitive efforts of the instructor’s expertise on display so as to reflect a way through which to analyze and think about a process. This style of communication may initially suggest an instructor’s vulnerability, as an analytical thought process is different for each person and the reflective efforts of the instructor on display may also be initially uncomfortable to make public within an instructional venue. However, allowing the learners to engage in this style of thoughtful understanding supports Schon’s work (1987) as framed through not only tacit knowledge, knowing in action and reflection in action.

As concerns the verbal and nonverbal cues of the learners, these efforts will represent themselves differently as based upon the learner personality and strengths, weaknesses and vulnerabilities of the learners. Meaning, the instructor’s presence within the course can support and strengthen the ability of the learners towards reflecting verbal and nonverbal cues of the learners, through innumerable differentiated means. One example may be through publicly thanking a learner for asking questions “early” and “often”, with special reference to the fact that this learner proactively engaged in querying the instructor for clarification

so that the rest of the course colleagues will have this support readily available when engaging in the course effort. Another example, may be to thank a learner for a private communicative request for explanation and support, with a follow-up request that the learner please consider sharing the question-answer effort with the other course colleagues so as to support everyone else within the course. These efforts may appear simplistic in nature, but engaging in a community effort towards course understanding and proactive effort not only highlights the proactive learner as knowledgeable, on task and reflective, but also as a collegial learner who is willing to share and support learner colleagues. This style of engagement and instructional presence more fully supports the learner’s ability towards representing verbal and nonverbal cues within a “safe” and supportive environment wherein questions and concerns are welcomed, appreciated and fully addressed due to the instructor presence and interest in the learners’ success. As well, instructor presence is also more fully engaged by addressing differentiated verbal and nonverbal cues of the learners through considering the non-stated concerns of learners. An example of this effort occurred recently, due to city-wide floods that impacted learners living within the area. One learner’s home was partially flooded and the vulnerability was reflected within the course environment through difficulty with scheduling team-based efforts. Instead of the issues focusing upon the scheduling angst, what was actually occurring was the learner’s upset by the team’s inability to emotionally support and differentiate previously scheduled meeting dates and times so as to support the learner who was in the midst of personal and professional chaos. The instructor presence and knowledge of the learners in the team reflected upon the angst-ridden communications by the one learner, considering nonverbalized word processed cues that required the instructor to not only offer a nurturing response and recognition to the current learner situation, while also attempting to subtly reflect upon the other team member’s differentiated responses to

difficult situations. Meaning, when different personalities find themselves in difficult situations, some persons “go with the flow” while others become more structured and display a need to maintain order, control and structure. Although this style of response to learner cues requires the instructor presence to move beyond a knowledge-based course understanding of the learners, the reflective efforts and understandings of differentiated learner needs and efforts within a course environment mandate the ability to more fully understand the differentiated meanings behind learner verbal and nonverbal cues.

The instructor who is a skilled professional has the ability to ensure their instructional presence to analyze the immediate context within the instructional environment and learner understanding, with the subsequent ability to seamlessly shift instructional efforts towards more fully supporting the learner’s subject matter understanding and engagement. The teacher’s ability to ensure their own cognitive and professional understandings as the lesson progresses, supports the learner’s through the ability to reflect in action. One’s own instructional practice and prowess supports the teacher presence.

Zeichner’s Three Levels of Reflection

Zeichner supports both Cruikshank’s and Schon’s understandings of reflective practice, but method, performance and practical, methodical proficiency may be considered necessary but not sufficient. Zeichner’s (1981, 1983; Zeichner & Liston, 1987) understanding of reflective practices is threefold, beginning with technical elements such as method and performance efforts with the primary impact being the instructional strategies and successes within the instructional environment. Reflecting upon these basic masterful elements of style and strategy are necessary and appropriate. Secondly, situational and instructional contexts are addressed within a reflective manner. Reflecting upon and analyzing why instructional contexts were implemented, as well as why situational contexts were

inherently appropriate within the instructional process are necessary. This also includes not only the straightforward curricular efforts and subject matter instructional efforts, but this also includes analytical reflections upon to what extent any hidden curricula or hidden agendas might be in play. A third level within Zeichner’s levels of reflection revolve around social justice and equity efforts, stated as moral and ethical issues upon which an instructor must analytically reflect. As stated by Adler (1991), “Reflections at this level asks that teachers become, in Henry Giroux’s (1988) terms, ‘transformative intellectuals,’ who are capable of examining the ways in which schooling generally, and one’s own teaching specifically, contribute or fail to contribute, to a just and humane society” (p. 11). Zeichner’s expectation that reflective instructors are fully present within the instructional process, not only towards addressing the instructional needs of the learners as regards working with the subject matter, but also towards social justice and equity concerns.

Motivational Needs of the Learner

The instructor’s presence has an inherent impact upon the learner’s sense of motivation throughout the instructional process. Maslow directly addressed the needs associated with motivational efforts on the part of the learner, specifically as framed through Maslow’s Hierarchy of Needs and associated understandings (1943, 1954, 1962, 1968, 1964/1970a, 1970b). The learners are supported by the instructor’s instructional presence and recognition of the inherent needs of the learners, towards engaging in addressing levels of deficiency needs (physiological, safety, social and esteem) and overcoming these needs, with the expectation being to strive towards ensuring that each learner reaches the learner’s level of growth needs (self-actualization). This hierarchy of needs, as delineated by Maslow, reflects the impact of the instructional presence within the learning environment; more specifically stated, the instructor’s presence and engagement with the learners

and within the instructional environment directly supports the deficiency needs of each learner more directly, with the desire towards supporting each learner's efforts towards reaching the self-actualization level that offers an engaged learner who may deftly engage with the subject matter, the learning process and the collegial learners at a level of growth and strength.

TEACHER PRESENCE: IMPLICATIONS WITHIN THE DISTRIBUTED LEARNING ENVIRONMENT

Within a distributed learning environment, the instructional presence of the teacher-facilitator is even more necessary than what may be perceived within a face to face traditional instructional environment or even a blended learning approach towards learning. Defining distributed learning environments as online and mobile learning environments, the instructional presence of the teacher-facilitator is enhanced due to the time and location concerns of presence. Towards addressing the teacher presence implications within the distributed learning environments, discussions revolving around motivational and cognitive support are offered; specifically, a focus upon facilitative instructor guidance, self-regulatory instructional efforts, cognitive load support systems and mentor-focused instructional efforts engage in motivational and cognitive support efforts more fully frame aspects of teacher presence with more specific implications within the distributed learning environment are fully engaged.

The motivational and cognitive support inherent within an instructional environment is even more pronounced within a distributed learning environment. As previously mentioned, Maslow's Hierarchy of Needs (1943, 1954, 1962, 1968, 1964/1970a, 1970b) supports an understanding of the deficiency needs and growth needs of each learner. However, the instructor's presence within the distributed learning environment is

necessary as *perceived* and *actual* presence support systems. Within this section's discussion, each aspect is inherently *perceived* instructional presence referring to the instructional facilitator's prior, asynchronous efforts towards supporting the learner's cognitive perception of teacher engagement; this may be perceived as previously recorded and available video, audio, slideshow and other forms of subject-focused materials that offer the perception of the instructor's presence and immediacy within the instructional environment for purposes of learner motivational efforts and perceived cognitive support structures, yet the instructor is not actually synchronously available "live" to the learner at that point in time. On the other hand, the *actual* instructional facilitator's presence in the course may be realized by the learners through synchronous efforts within the course structure such as video conferencing, telephone conversations, texting, chats, and other synchronous events that reflect the true timely availability and structured teacher presence of the instructional facilitator. Even though the learner and instructor have differentiated time and location realities, the availability of the instructional facilitator within an easily available and less structured environment offers motivational and cognitive support for the learner who desires or requires non-traditional teacher presence so as to perceive a sense of well-being and engagement within the bounds of the distributed learning environment.

Facilitative Guide

Within an instructional environment, the instructor's presence is offered as a facilitative guide. The instructor engages in the efforts towards being a "touch point" within the instructional process, towards ensuring that each learner progresses naturally and within a supported manner through the instructional environment. Facilitating the learner's efforts within a course environment may be perceived as not only motivational in nature, but also towards supporting the learner's ease of environmental understanding which may be per-

ceived as supporting the learning environment's usability on the part of the learner. As a facilitative guide, the instructional presence also supports a stronger understanding effort revolving around the subject matter, introducing new subject-specific information within a timely fashion.

Self-Regulatory Maven

The instructor's presence within the instructional environment more fully supports the concept of a self-regulatory maven. Self-regulation is an area of study that is fully framed within all types of instructional environments (Schunk, 1994; Schunk & Zimmerman, 1997, 2003; Zimmerman, 1989, 1990, 1994) and strongly reflects the needs of the learner towards fully framing the learner's ability to naturally control and progress through an instructional structure. As Zimmerman describes a self-regulated learner, "They approach educational tasks with confidence, diligence, and resourcefulness. Perhaps most importantly, self-regulated learners are aware when they know a fact or possess a skill and when they do not" (1990, p. 4). Although a self-regulated learner is recognized as controlling one's own environment and controlling one's own learning, recognition must be offered towards the instructional facilitator's presence towards also supporting the learner's efforts towards self-regulation. A self-regulatory maven not only designs support structures into the instructional environment towards guiding and supporting the learner, but the strength of environmental usability and clarity of expectations is also a supportive self-regulatory maven's strength.

Cognitive Load Support System

Within distributed learning environments, the teacher presence is inherently integral. The instructional facilitator's efforts towards supporting the learner's cognitive load efforts works towards ensuring that the learner's efforts towards understanding the subject matter are not overwhelming in nature. The introduction and representation of

information within a learner's working memory can be overwhelmed with too much information offered too soon within a learner's progressive understanding of the information, reflecting a cognitive load issue (Chandler & Sweller, 1991, 1992, 1996; Sweller, 1988, 1989, 1991, 1994; Sweller & Chandler, 1994; Sweller, Chandler, Tierney & Cooper, 1990; Sweller & Cooper 1985; Sweller & Levine, 1982; Sweller, Mawer & Ward, 1983; Sweller, Van Merriënboer, & Pass, 1998; Ward & Sweller, 1990). As quoted from Sweller (1994), "The difficulties we face when learning new intellectual tasks can fluctuate dramatically. Learning can vary from being trivially easy to impossibly hard. Some of the reasons for variations in ease of acquisition, such as changes in amount of information, are obvious" (p. 195). The instructional presence within the distributed learning environment supports the learner's efforts, so that the "trivially easy" cognitive efforts are opportunities are initial opportunities for the instructor to engage in appropriate cognitive efforts through teacher presence efforts, so that the "impossibly hard" cognitive efforts of the learners have been previously supported by prior teacher presence efforts and the learners may have developed a level of comfortableness with the instructional facilitator so that communicative and relational efforts towards understanding the subject matter will have already become natural progressions in understanding on the part of the learners.

Mentor-Focused Instructional Efforts

The instructional facilitator within the distributed learning environment engages in a community of practice environment (Lave & Wenger, 1991; Wenger, 1998, 2009, 2010; Wenger, McDermott & Snyder, 2002) wherein an instructor's presence may be reflected as a mentor-style relationship wherein the instructor holds a mentorship role and the learner holds an apprenticeship role. Within this instructional environment, the instructional facilitator engages in a style of presence wherein the learner's efforts revolving around the subject

matter are guided and supported by the instructor's efforts. Within this framework of instructional effort, three areas of emphasis are recognized as imperative: cognitive understanding; higher order thinking skills; and, subject matter engagement.

Cognitive Understanding

Within a mentor-focused instructional effort environment, the learner's cognitive understanding revolving around the subject matter is constructed and supported by the instructional facilitator's presence, inherent within the instructional design process, the subject matter discussions that may integrate additional subject matter discussions, ways of looking at the information through different lenses of understanding and thought process, as well as a Socratic questioning effort wherein a style of thoughtful yet disciplined dialogue ensues, towards logically reviewing the subject matter in different ways of meaning and validating those understandings through checks, balances and engaging in new and different understandings of the subject matter.

Higher Order Thinking Skills

Integrally important within the instructional environment is the instructional facilitator's presence and engagement with the subject matter and the learners, towards slowly working with the subject matter from lower order thinking skills engagement (knowledge, comprehension and application) towards higher order thinking skills of analysis, synthesis and evaluation, as framed through Bloom's Taxonomy of the Cognitive Domain (Bloom, 1956, 1984; Bloom, Englhart, Furst, Hill & Krathwohl, 1956; Bloom & Krathwohl, 1956; Krathwohl, Bloom & Masia, 1964). Further, Anderson and Krathwohl's revised Cognitive Taxonomy for the Digital Age (2001) suggested a shift from the lower order thinking skills designations of remember, understand and apply, with the higher order thinking skills designations framed

as analyze, evaluate and create. The instructional facilitator's presence within the learning environment supports the learner's efforts from the basic level of knowledge acquisition and remembering, slowly progressing from the novice subject matter understanding through the differentiated levels of subject matter cognitive efforts, with the desired engagement of the learner with the subject matter at the higher order thinking skills levels. The teacher presence further supports and engages the learner's efforts within the instructional environment, shifting the learner's understanding over a longitudinal period from novice towards developing an enhanced understanding of the subject matter.

Subject Matter Engagement

The subject matter engagement within the distributed learning environment is multifold for the learner, as well as for the instructional facilitator. Much as was described within the previous discussion, the ability to work with the subject matter in novice levels of engagement and then slowly engaging with the subject matter in new and cognitively differentiated manners is vitally important towards more fully reflecting the learner's successful attainment of information from a learning environment.

SOLUTIONS AND RECOMMENDATIONS

Further understandings revolving around the teacher presence and need within an instructional environment is vital. Towards addressing different recommendations towards supporting teacher presence within the instructional environment, whether face to face or blended or online learning environment in nature, suggestions towards solutions are necessary. One recommendation is towards supporting a novice instructor's teacher presence through a mentorship style engagement.

One style of mentorship may reflect a teaching assistant style of training effort wherein the expert instructor supports and engages the novice instructor in an appropriately timed engagement with the learners. The mentor would not only model differentiated teacher presence engagement to the novice instructor, but also engage in extensive reflections and explanations as to the reasoning and past experiences that have led to each approach. Another style of mentorship could be a “guide on the side” approach, wherein the expert instructor would take a voyeur’s stance towards supporting the novice instructor’s teacher presence engagement. The expert instructor may engage in online courses as merely a silent administrative access role, to “check in” and look around the course environments to see what is happening and consider ways to support the novice instructor. On the other hand, the expert instructor and novice instructor may desire a less proactive effort, wherein the expert instructor may choose engage in a support style that requires the novice instructor to communicate and request the mentor’s support and guidance when requested. The primary concern with this style of “hands off” approach is the lack of teacher presence understanding that may be unrealized by the novice instructor; understanding the ability to recognize what is not yet understood is imperative within this style of mentor effort, as the concept of “I don’t know what I don’t know” may be detrimental to the course experience of the learner as well as the novice instructor’s developing understanding of the ebb and flow of a learning environment and the associated development of the learning community. The concept of discourse throughout an instructional environment is necessary and appropriate, while the teacher’s needs towards delving into reflective practices will more so engage instructors towards understanding the needs of the learners, the engagement with the subject matter, as well as the motivational and cognitive support needs of the learners.

FUTURE RESEARCH DIRECTIONS

Emerging trends revolving around distributed learning environments, especially within the realm of mobile learning, articulate a need for strengthened understanding of the teacher presence impact upon learners. Instructional facilitators may naturally engage in aspects of teacher presence, but the implications towards future research directions more fully articulate impactful research efforts and associated professional development needs of all instructional facilitators. An initial consideration towards future research directions is focused upon a differentiated thought process, wherein a “one training event” episode is not sufficiently adequate towards developing a strong instructor who can implement teacher presence at a high level of quality engagement. Of course, there are innumerable talented individuals who have the ability to develop their own understanding of successful teacher presence within an instructional environment; however, a focus upon continuous professional development is necessary and appropriate. Continuous support and knowledge base extension through the sharing of ideas, talents and tips by instructor colleagues may be offered as inherently quick and useful short professional development vignettes that develop important reflective efforts and instructional design thoughts of instructors who desire to enhance their instructional presence as well as learner satisfaction.

CONCLUSION

The background understandings of discourse, reflective practices and motivational needs of the learners are merely a beginning understanding of teacher presence within a distributed learning environment. More fully understanding teacher presence through motivational and cognitive support of the learners is integrally important,

especially as distributed learning environments become more viable instructional environments wherein a strong teacher presence is necessary and appropriate.

KEY TERMS AND DEFINITIONS

Cognition: The way that people think, work with and understand information.

Discourse: Discussions within a social environment, towards more fully understanding the knowledge, towards checking and double-checking one's understanding of information within a social context.

Mentor: A guiding force, meant to support the needs of an apprentice.

Motivation: The desire to move forward, to engage more fully.

Presence: Engagement within the environment, engagement with the subject matter, and availability for the learner.

Reflective Practice: The ability of a person, specifically an instructor, to analyze their actions and understandings within an instructional environment.

Self-Regulation: The ability to control one's actions and reactions.

Virtual Worlds in the Educational Context

INTRODUCTION

Information and Communication Technologies (ICTs) are changing the daily activities of human beings, promoting the process of teaching and learning, facilitating the construction of knowledge. In recent years, ICTs are becoming stable in the educational context, as they allow different ways of presenting content to students (Quintana and Fernández, 2015). Technological resources to support the transmission of knowledge can be represented by heterogeneous formats, such as simulations, games, virtual worlds, videos, animated agents and avatars, web pages, among others.

Virtual worlds appear as technological tools to support construction of knowledge and for this reason has been the subject of study by different researchers over the past few years. There are many educational institutions that use virtual worlds, as they offer to the student an interaction similar to the real world, permits the student to get involved with various activities and learn in an interactive way, acquiring new skills (Mateu et al. 2013). Hulsey, Pence and Hodges (2014) point out that, students represented by avatars can get a better learning experience watching and/or participating in practical activities in virtual worlds.

Abreu et al. (2012) argue that the process of application development focused on education, in addition to the use of principles stemming from

Software Engineering (e.g. extraction requirements, requirements analysis and modeling), should be concerned with the incorporation of learning theories.

There is scientific evidence that shows promising results when researchers link pedagogical concepts in the construction and application of educational systems. Virtual learning environment Moodle, for example, was designed and developed from social constructivist epistemology (Moodle, 2016). Currently, numerous educational institutions, to support the process of teaching and learning, use this environment. In the field of virtual worlds, Nunes et al. (2016) show that use of Mastery Learning theory in the context of virtual worlds for education contributes to reveal optimistic results regarding performance advancement to the students.

Seeking to identify learning theories used in virtual worlds applied in the educational context and obtain an overview of what is being researched and developed in this area, as for in order to investigate the scientific production related to the theme and highlight possibilities for future research, this chapter has order to present a systematic review of literature. Thus, primary studies were researched in article format, indexed by journals and international conferences, considering the period of last five years (2010-2015). To achieve this, research questions was created aiming to consolidating quantitative and qualitative information found.

To present the research conducted; this chapter was organized with a descriptive section about the concepts inherent in virtual worlds, contextualizing the reader about this area. It is also presented some of the currently existing major difficulties and problems in this area, and later presented the listed research and analysis of the results obtained in this study. Finally, future directions for the application of virtual worlds in education and final considerations of this chapter is presented.

BACKGROUND

Also known as, immersive virtual environments, virtual worlds are tools that permits reproducing aspects of the real world or fantasy in a virtual space, providing its users a controlled environment with numerous opportunities and experiences. Griol et al. (2014) corroborate stating that three-dimensional spaces are simulated by computer, which can be exploited in first or third person, through a graphical representation called avatar.

Increased use of virtual worlds in different application contexts, allowed their inclusion in the educational field, from which emerge new opportunities for use of these computing resources as support and even motivation in the learning process of its members. In this sense, is possible to claim that these immersive environments, besides offer a combination of simulation tools, which enhance user interactions and consequently the way they learn, also provide a sense of immersion, as well as the opportunity for communication and collaboration between its users, justifying its application in activities related to the educational field.

There are several possibilities to be explored using virtual worlds applied to education, e.g., as the extension trend of real laboratories for virtual environments, which according to Nunes et al. (2014), is possible offer new opportunities without costs and risks to users, besides to offer opportunity to operating virtual equipment's in controlled environments. It also offers easy access feature and available at all times; immediate

feedback; expertise distributed among users, where exchange of experiences with each other is possible; student-centered learning; and encouraging for practice of authorship.

In virtual worlds, besides users interact with three-dimensional and multimedia objects, they have the possibility to explore the interaction with other connected users using chat to communicate via instant messaging or through voice communication. This feature enables users to build their knowledge jointly, where each student can cooperate with a colleague, e.g., assisting in the resolution of a particular activity or simply discussing their understanding of a topic addressed during their interactions.

Several investigations in different areas has shown the use of virtual worlds with promising results, as well for building scenarios and attractive three-dimensional objects to improve user interactions and promote learning. Implementation of these environments demand that several factors be considered for development, such as: educational objectives, teaching strategies based on learning theories, friendly and instructional design, objects, experiments and exercises that encourage interaction and collaboration among users, besides passing the feeling of being immersed in the environment (Herpich et al., 2016).

ISSUES, CONTROVERSIES, AND PROBLEMS

Taking into account the theoretical review presented above and expertise of the authors of this chapter, it was possible to make a number of considerations about some of the main problems that are included in the scope of this study, specifically the implementation of educational activities in virtual worlds. First, it becomes possible to identify an important point when comparing to a virtual learning environment like Moodle, where these have been developed with specific features for educational use with students, while the virtual worlds need to be adapted to use with this propose.

Because of this adaptation, it becomes important to use programming features through OSSL and LSL language in the virtual world, so they can be inserted into different types of learning materials such as videos, slides, text, links and questions. In addition, simulation of experiments about a particular phenomenon also become complex, as there is a demand for a deeper level of knowledge on the part of the developer to create such resources.

At this point it becomes important to highlight the user's learning curve to use the virtual world, where its basic use can be considered fast to be learned and enjoyed by its users. Regarding the creation of more complex features that involve programming scripts, this process has become costlier, from the moment that makes necessary the use of programming logic and algorithms, as well as other aspects relating to the manipulation of 3D objects in the environment.

VIRTUAL WORLDS APPLIED IN EDUCATION

This study is characterized as a systematic review of the literature. In this perspective, seeks to evaluate and interpret primary research to achieve secondary research objectives (Kitchenham et al., 2007). It was conducted in four phases: (i) definition of the scope of this review; (ii) search and selection of primary studies; (iii) data extraction; (iv) analysis and synthesis.

First phase consisted of the design of the period, in which, the primary research was socialized, covering the range of 2010 to 2015. In addition, the languages of primary research were defined as being Portuguese and English. Five research questions were elaborated, the main bases of scientific data were selected, was constructed a string search, and inclusion and exclusion criteria were established. Seeking to achieve the review objectives, the following research questions (RQ) were structured:

- RQ1:** How are distributed and what are the developments of the investigations over the years?
- RQ2:** What conferences and journals that have the highest number of published articles?
- RQ3:** What are the trends in the context of Virtual Worlds in Education?
- RQ4:** What are the most used learning approaches in the context of virtual worlds applied to education?

To answer these questions, were chosen the following databases (the names in Portuguese was maintained):

- Congresso Internacional de Informática Educativa or International Conference of Educational Computing;
- Workshop de Informática na Escola or Computer Workshop in Schools;
- IEEE Transactions on Learning Technologies;
- IEEE Transactions on Education;
- Congresso da Sociedade Brasileira de Computação (Workshop sobre Educação em Computação) or Congress of the Brazilian Computer Society (Workshop on Computer Education);
- Journal of Virtual Worlds Research;
- Revista Latinoamericana de Tecnología Educativa or Latin American Journal of Educational Technology;
- Simpósio Brasileiro de Informática na Educação or Brazilian Symposium of Information Technology on Education;
- Computers & Education;
- Revista Novas Tecnologias na Educação or Journal of New Technologies in Education;
- Creative Education;
- Informática na Educação: teoria & prática or Computers in Education: Theory & Practice;
- IEEE Computer Graphics and Applications;
- IEEE Revista Iberoamericana de Tecnologías del Aprendizaje or Iberoamerican Journal of Technology Apprenticeship.

To locate the primary research in the stipulated databases, the string search, based on the research questions, was established. String search was composed of keywords considering its versions in Portuguese and English. In some databases where was not include the automatic search, manual search method was applied.

The string consists of the following operators: “AND”, “OR”. Thus, the logical OR operator is used to indicate that there are alternative terms and “AND” is used to connect two terms, as it can be seen in the following:

- (“mundos virtuais” OR “ambientes virtuais imersivos” OR “ambientes imersivos” OR metaversos OR “mundos digitais virtuais 3D” OR “ambientes virtuais multi usuá-rios” OR “virtual worlds” OR “immersive virtual environments” OR “immersive environments” OR metaverses OR “digital virtual worlds 3D”) AND (educação OR ensino OR aprendizagem OR education OR teaching OR learning).

To determine the inclusion of articles, considering some factors that identify the relevance of primary research to address the research questions, inclusion and exclusion criteria were created (Table 1). They were used as parameters to aid in the screening of publications.

In the second phase of the research, there was the implementation of the search string in the selected research sources, aiming to collect primary research. 419 articles were founded in the initial search and databases of IEEE Transactions on Education did not return results. Localized items passed to the third stage of the research.

In the third phase, were used the inclusion and exclusion criteria defined during the planning (phase I), were classified as accepted or rejected. This phase consisted of reading the titles, abstracts and keywords of 419 articles, were at end of this process only remained 113 included and 306 excluded articles. Later, still in the third phase, 113 articles were fully analyzed and criteria for

Table 1. Inclusion and Exclusion Criteria

Inclusion Criteria	Exclusion Criteria
IC - 1: Presents the virtual worlds applied to education in various fields of study and platform independent.	EC - 1: Not addresses the actual application of virtual worlds in education, i.e., only has one of those terms in the article.
IC - 2: Presents results that are consistent with the objective listed in the article and the instruments used in the evaluation of virtual worlds applied to education.	EC - 2: Technical reports, documents that are available in the form of summaries or presentations and secondary literature reviews.
	EC - 3: Only addresses theoretical and philosophical aspects (without technical definition, methodology, etc.).
	EC - 4: Not presents the results clearly and instruments used in the evaluation of virtual worlds applied to education.
	EC - 5: Papers written in a language other than English or Portuguese.

inclusion and exclusion were applied. 58 articles were included and 55 were excluded. A complete re-reading of the publications taken in the final phase was conducted, i.e., 58 articles were read again considering the inclusion and exclusion criteria. Finally, remaining 24 included articles and 34 were excluded. Is important to emphasize that the reading held at the end of the third stage, sought to remove the items that did not mention the use of learning theories in virtual worlds.

In the fourth stage of this research, the remaining articles were analyzed and categorized, in order to answer the research questions and therefore the objective of this research. This step is detailed in the next section.

ANALYSIS OF RESULTS

Initially, a comparative analysis considered the 24 articles included and excluded 34 at the end of the third stage. This analysis seeks to highlight the databases that have studies about virtual worlds

Table Legend: EB – Electronic Base; IR – Initial Result; I – Included; E – Excluded.

applied in education that uses learning theories. Figure 1 presents a comparative distribution of the publications, which highlights the number of articles that used educational theories in their studies and the number of articles that do not cover educational theories.

In Figure 1, you can see that most of the publications found are from Computers and Education, which represents 41% of articles that mention the use of learning theories. Articles from IEEE Transaction on Learning Technologies and Latin American Journal of Educational Technology differs from others surveyed, because it contains only articles that discuss the use of learning theories to explain the process of learning in virtual worlds. Analyzing the articles selected, was possible to trace some influences of the major figures of the

field, like theories of Papert's, Piaget's, Ausubel's, Vygotsky's and Kolb's.

One of the current challenges in the area of virtual worlds is related to authorship of users who do not have specific technical knowledge, to build and manipulate multimedia features in this type of environment. Researches related to learning of foreign languages and teaching of computing topics, such as algorithms and programming, can use features presented in virtual worlds to instigate the user to become more active and exercise his critical through by the manipulation and construction of knowledge on their own.

It is in this scope that some authors of the articles selected sought to anchor the constructionist theory proposed by Papert (1997), in which the user performs the construction of knowledge through

Figure 1. Data from articles included and excluded

concrete actions, resulting in an actual product and from your interest. Features such as creating objects, manipulating educational activities and exchange of information through the chat are some of the points present in these environments, which fits into this educational approach, allowing its use in several articles found.

Another great thinker related to construction of knowledge is Piaget (1973), in which his psychogenic theory has also been used as an educational base for the construction of activities in virtual worlds. The use of virtual worlds for teaching physics with simulations of phenomena that occur in the virtual world makes room for the application of this theory.

The dynamicity of simulations in virtual worlds, where its parameters can be modified to change its mode of operation and therefore the end result, forces users to exercise their knowledge of this topic to understand what happened during the process. Thus, based on the theory proposed by Piaget, the individual acts on objects in a physical or mental form, causing the occurrence of an imbalance of the knowledge that he

had acquired previously, which is established as cognitive conflict.

To resolve this conflict, the author describes that student must carry out the process of assimilation and accommodation of new knowledge, which affects the balance of the same, thus allowing to suffer another imbalance and thus restart the process. In the case of simulations in virtual worlds, it can encourage the user to perform new actions that were being analyzed based on the concepts that held, in order to cause an imbalance, to be organized again and there is an accommodation of knowledge.

Other items were also found that seeks to instigate users to learn content related to the areas of physics and chemistry, through the creation of virtual laboratories with simulations of various types of experiences. The possibility of creating virtual 3D animated objects, which reflect experiments that occur in the real world, allows complementary practical theory that is seen in the classroom.

Thus, authors have used as an educational basis of the theory of experiential learning of

Kolb (1984), which explains learning as the process by which knowledge is created through the transformation of experience, the knowledge results from the combination of understanding and transforming experience. In virtual worlds, it can be carried out this cyclical process in an organized and structured way in teaching activities done by students. The concepts are explored and viewed through 3D simulations, which can be further discuss issues involving these experiences.

At this point, it can also be driven together with this approach the learning processes of problem based on an experiment in field of algorithms and programming. Such an approach can come to cover the entire cyclic process present in experiential learning and also enter in problem solving to assist in student learning in this research topic, using an auxiliary software to create codes and view the results of the algorithm on the objects in the virtual world.

With regard to articles that addressed the use of serious games in virtual worlds, challenges combined with existing knowledge in cognitive user structure and those who should be acquired with the game opens the possibility for the use of meaningful learning proposed by Ausubel (1963). From the moment that the game can be planned so that the user has to have certain knowledge about a topic to meet the proposed challenges and advance of phase, it exercises the use of previous concepts to learn new topics that are presented on the challenges.

An example of serious game of an article analyzed seeks to help student's knowledge in computer networks, in which, after viewing a particular content in the classroom, students can play in the virtual world seeking to strengthen the process of acquiring a significant learning about a topic, as well as to use this knowledge to solve challenges on topics which does not have much knowledge.

In the case of Vygotsky's theory (1978), which discusses concepts of the zone of proximal development (ZPD), the author explains that there is a potential for cognitive development in guid-

ing the gap between the growth capacity of the individual point view of an individual, with the resolution of problems through the help of people or groups who have a more advanced knowledge of the subject. The issues proposed by this thinker can be embedded in the context of virtual worlds because of the possibility of communication and collaboration in the environment.

Features, such as the use of chat and the possibility of building objects and activities in joint authorship in virtual worlds fall on the principles defended by Vygotsky. The interaction between avatars with conversations using chat can be useful for the development of activities that are based on existing provisions in the ZPD, as well as its teacher or educational tutor can come to assist in solving problems during an interaction in the virtual world.

Reported several features present in virtual worlds and theories surrounding the use of these that have been proposed by the great thinkers of the educational area, it is important to also highlight an important concern related to cognitive load level of user's in virtual worlds. The theory of cognitive load proposed by Sweller (2003) explains that learning occurs in a better manner when the information's are aligned with human cognitive processes, that is, when the volume of information provided to the student is compatible with the ability of human understanding. Thus, it was found that some of the selected studies have examined in the context of virtual worlds certain aspects of the user perception, didactic instruction and comfort level that can be considered appropriate for the context of the user, so that there is not a cognitive overload, especially due to various possibilities of interaction and visualization present in virtual worlds.

Analysis in this section creates the possibility to draw a certain line of influence of some of the leading thinkers of education mentioned above with certain areas, educational topics and forms of exploitation of the resources present in virtual worlds. It is noteworthy that such links and analyzes are only based on selected articles in this

research, not seeking to generalize and draw labels that define the use of a particular educational theory in an educational area. Thus, it seeks to make clearer to readers of this chapter as certain situations and research problems are likely to fit into certain educational foundation for building experiments in virtual worlds.

Explained the main points, concepts and applications of virtual worlds in various educational theories identified during the analysis of the selected studies, it was possible to make a brief description about these issues and clarify to readers of this chapter some of the peculiarities present in each of the cases described. The following section presents some of the future directions contained within virtual worlds applied to education.

FUTURE RESEARCH DIRECTIONS

Virtual worlds have had their expansion in the last two decades, which in recent years has been carried out a significant number of experiences in various fields of education, such as chemistry, physics, engineering, computer science and many others. The analysis in this chapter has shown an important variety of options regarding the choice of an educational theoretical basis to support formulation and implementation of teaching strategies and teaching activities with students of different age groups.

Conducting simulations of experiments and construction of learning activities in virtual worlds tend to continue growing, to the extent that results obtained from research has been positive and instigators. The favorable scenario for the application of educational theories in virtual worlds opens up a broad field of possibilities in this scope, allowing increasingly exploit the use of computing resources present in these environments, to perform activities with students during the class period, at distance or as complementary to reinforce contents seen in classroom, where the application of flipped and blended learning can be explored within this context.

Throughout this chapter, the authors sought to meet the objectives previously established, as well as develop a theoretical collection about virtual worlds applied to education, in order to contribute to the researchers who are starting or looking for the best use of strategies of these virtual immersive environments in the educational sector. For this, an analysis in various contexts was performed by discussing the different educational approaches used in various areas of knowledge and education levels.

Based on evidenced findings, the authors qualify as future directions of research in this area, the need to establish a line of investigation seeking evidence that motivational elements and of engagement can be implemented for the involvement of users in these virtual worlds with resources for learning thereof, analyzing from primary strategies, e.g., use of videos, slides, images, sounds, objects and 3D animations, even applications involving the use of theories as flow, gamification, learning trajectories, among other strategies were also revealed in this systematic review.

CONCLUSION

This chapter presented a systematic review, in which, it was possible to identify different educational theories that have been used as a theoretical basis for the formulation and implementation of educational activities in virtual worlds. It was found that research has been applied in different areas of education, especially in the fields of chemistry, physics, engineering and computer science, which can be developed various types of simulations in 3D environment representing real-world phenomena.

An important point to note is the existence of a wide range of possibilities to be deployed in virtual worlds concerning the use of educational theories, in which, was established that characteristics of immersion, active learning, communication, collaboration and interaction, that are present in this environment, open a very wide range to be

worked in different educational concepts present in several theories.

This possibility has resulted in the development of a wide range of research in the past few years, in which different approaches and applications of methodologies informed by one or more educational theories have been the subject of research by authors. Results have been positive, instigators, and help to improve the learning process of students, mainly due to the integration of these theories to the elements present in virtual worlds.

For the final considerations of this chapter, the authors of this study believe that this type of approach can be considered valid and with a great potential, to be explored in different research that can be carried out. It is expected that readers have been able to improve their knowledge in the areas of virtual worlds applied to education, including its theoretical foundations, difficulties and applications. Thus, the authors envision that this chapter has provided a better understanding about the integration of these approaches, explaining the steps taken to carry out such processes and how to carry out this approach in new research that may arise from this chapter.

KEY TERMS AND DEFINITIONS

Educational Theories: A formal thinking that searches to resolve and instruct, as to explain how students can understand and construct knowledge in education.

Virtual Learning Environment: Environment that seeks to provide support to teachers, managers and student in planning, construction and execution of educational activities, as for the insertion and make available educational materials.

Virtual Worlds: Are tools that simulate the real world in a three-dimensional environment, providing users the sense of immersion in a controlled environment with many opportunities and experiences.

Anger and Internet in Japan

Hiroko Endo

Rissho University, Japan

Kei Fuji

University of Tsukuba, Japan

INTRODUCTION

The world has changed a lot due to the Internet. Japan is no exception and has become a society where people can freely share their opinions, thoughts, experiences, and personal emotions to a large number of people all over the world. It is reported that 94.6% of people in Japan use a cellphone or smart phone (Ministry of Internal Affairs and Communications, 2015), and the spread of mobile devices which allow easy access to the Internet no matter the time or location is fueling people's active sharing of opinions and expression of emotion.

However, this has given rise to a new problem unlike anything seen before. An unspecified large number of people's anger, complaints, criticisms, and offensive language not like anything seen in the real world is spreading on the Internet and continuing to cause uproar.

First off, this chapter will first focus on anger expression on the Internet in Japan by presenting a few examples. It will also highlight the results of large-scale studies relating to anger expression in Japan. Second, it will explain in terms of "Social Sharing" what sort of psychological effect sharing one's anger with others has, as well as go over an empirical study that demonstrated where social sharing of anger on the Internet has no positive effect. Third, it will show the results of studies done in Japan which described emotional experiences to look at how we should control our anger. It will also discuss what care should be taken when expressing emotions and experiences of anger on the Internet. Finally, it

will consider what main factors are needed to prevent the problem as above by re-examining the relationship between the Internet and anger from a new perspective.

BACKGROUND

Many readers out there likely took pleasure in watching the 2016 Rio de Janeiro Olympics. All of us were excited by the sight of top athletes gathering at the Olympic flame and showing their inflamed passion for sports. But that excitement can also easily lead to flaming on the Internet. Such a situation had already occurred during the 2000 Sydney Olympics. There was an incident where the athlete Shinichi Shinohara from Japan was judged to have been defeated in the final match for Men's Judo in the over 100Kg class. Shinohara had countered his opponent with an Uchi-mata-sukashi at one minute and 35 seconds from the start of the match and taken a victory pose, but judges did not award the Ippon victory that he had deserved and instead judged in favor for his opponent. Immediately afterward people took to the Internet in Japan and there was an outpour of rage against the chief judge for what was referred to as the "greatest misjudgment of the century". But the flaming did not stop there and spread to other places that were not involved in any way. Since the chief judge for the match was from New Zealand, people ended up targeting the Embassy of Japan in a fit of rage and caused the site to become inaccessible (Tashiro & Orita, 2012).

DOI: 10.4018/978-1-5225-2255-3.ch691

One person's opinion can be shared between others who share the same opinion or thoughts and lead to an increase of supporters, which can garner much attention. This phenomenon has been likened to a waterfall by Sunstein (2011) and referred to as a "cyber cascade". In Japan this is more likened to that of a small spark suddenly erupting and causing an inextinguishable fire and is generally referred to as "flaming". Aside from the difference between water and fire, either one is an extremely appropriate metaphor for anger that should have been constricted to the emotions of individual suddenly transforming into the anger of a group or whole society.

ANGER EXPRESSION ON THE INTERNET IN JAPAN

There are many other examples of flaming on the Internet that also cover a range of other topics. One dramatic example in particular was for the 2011 Great East Japan Earthquake. The unprecedented major earthquake and tsunami on March 11 as well as the damage incurred from the continuing aftershocks brought much shock and grief to the whole nation. The damage was not confined to natural disaster and also caused the Fukushima Daiichi nuclear disaster, forcing neighboring residents to evacuate to far away land. The grief and anxiety that people experienced in this earthquake was also clearly expressed on Twitter. The number of tweets on that day rose to 33 million which was an increase of 1.8 times that of a normal day, and 70% to 80% of all tweets within the country for the following week after March 11 were related to the earthquake (NEC BIGLOBE, 2011). Many of the tweets showed people's concerns for the earthquake and tsunami and fluctuated to a constant cycle that reached a peak at late hours of the night (Miura, Komori, Matsumura, & Maeda, 2015). In short, it is surmised that people affected by the disaster were sharing their concerns with one another through Twitter whenever the night came.

What also deserves attention is that fact that a characteristic fluctuating pattern was observed in relation to people's anger regarding this disaster. This pattern matched with the timing of news reports concerning the nuclear power plant accident (Miura et al., 2015). The number of angry tweets was increasing whenever the mass media exposed the worsening of the situation with the nuclear accident, the government's delayed response, and unclear reports of the situation from the power company. From these examples we see that even when, or indeed because of being in the midst of a large-scale disaster, people's anger reaches massive levels through the Internet and can have various effects on society.

In recent years, a large-scale web survey study was conducted based on the present condition of flaming on the Internet. The study, conducted by Tanaka & Yamaguchi (2016), surveyed 19,992 participants regarding their awareness of flaming on the Internet and their experience participating in such. Only 7.09% of respondents said they had not heard of flaming, while a majority said that while they had heard of it, they had never seen it (71.35%). We therefore find that the issue of flaming is being recognized as a serious problem in society even by those who have never seen it for themselves. Meanwhile, it was reported that only 1.52% of respondents said that they had either flamed once or more (Tanaka & Yamaguchi, 2016). When considering the bias of being a web survey, that number is assumed to not surpass 1.11%. In other words, contrary to the general image that may exist, only an extremely small amount of participants in flaming intimidate others online.

When we look at it this way, it would seem that flaming is not that serious of a problem. However, focus should be brought to a follow-up study done by Tanaka & Yamaguchi (2016) concerning the attributes and psychological factors behind the participants in flaming. Results showed that men were significantly more like than women to participate in flaming, the younger they were, and the more frequently they used social media (see Table 1). What is notable here is that it was also

found that those with higher personal or household income or those with children were more likely to participate in flaming. These results are understood to reflect the fact that, for example, families with children or families with a financial base for supporting childcare would have a strong interest in protecting their children and thus be more prone to transitioning to such radical behavior.

Another important point is that those who have had an unpleasant experience being spoken to in a rude manner on the Internet or those who have no problem criticizing others with harsh language on the Internet are more likely to participate in flaming (Tanaka & Yamaguchi, 2016). To put it simply, those who have been met with slander on the Internet do not refrain from doing the same based on that experience, but instead become an active participant. In short, we can say that there is a negative chain of slander that is occurring on the Internet. This negative chain is reinforced by the thought that slander on the Internet is permissible, and can be linked to the process of new aggressors being produced with the increase of other victims. In this sense, even though the number of people who participate in flaming on the Internet is small as previously mentioned, that number is likely to increase. 2011 was a turning point that saw a tremendous increase in the number of incidents of flaming on the Internet in Japan, and is likely to continue that way (Yamaguchi, 2015).

EFFECT OF SHARING ANGER ON THE INTERNET

So what sort of psychological effect or benefit is there for people by expressing anger on the Internet and sharing that anger with a large number of people? Does anyone calm their anger by flaming on the Internet the previous night and wake up the next morning feeling refreshed?

To consider this issue, we will reference the social sharing of emotion. Social sharing of emotion refers to the inter-personal action of someone who has experienced an emotion sharing their

Excerpt from Tanaka & Yamaguchi, 2016.

experience relating to that emotion with others (Rimé, Mequita, Philippot, & Boca, 1991). Rimé, Mequita, Philippot, & Boca (1992) conducted a detailed analysis regarding this phenomenon through a series of studies which indicated the following various opinions. First, a vast majority making up 90% of people who have had an emotional experience have done social sharing. Although this survey was carried out in Belgium, Southern France, Germany, Spain, and Italy, no large cultural differences were seen in the act of social sharing, which demonstrated how much of a cross-cultural phenomenon it is. No gender or age difference was found either, confirming that it was broadly occurring. In short, people cannot resist talking with others when having experienced some kind of emotion. Second, such social sharing of emotion did not differ between varying types of emotion and was found to have occurred the same way whether it was a positive or negative

emotion. In other words, people feel the need to share with others regardless of whether they are happy, sad, or anger. Third, approximately 60% of people shared their emotions with others within the day that they experienced an emotional episode. The extent of social sharing of emotion (the number of times sharing was done and the number of people shared with) was found to be more likely to occur the stronger the degree of emotion which occurred in that episode.

What is particularly interesting is results indicate that the social sharing of such emotions goes against what is generally believed and does not contribute to recovering from negative emotions. An *expeRimént* conducted by Zech & Rimé (2005) demonstrated this. Zech & Rimé (2005) conducted this *expeRimént* by randomly assigning groups to those who recalled negative episodes, which was divided between those who shared the reality of the incident with others, those who shared an emotional perspective, and those who did not share anything. They then checked to see what effect social sharing of emotion had for recovering from negative emotions by having participants visit the laboratory both one week following the *expeRimént* and once more two months later to ask them to respond to a question sheet that measured the state of their negative emotions in response to the incident that they recalled during the *expeRimént*. Results of the *expeRimént* did not demonstrate any significant difference in relation to scores for negative emotions between the three conditions. The only thing that had a significant influence on reducing one's negative emotions was time, and whether or not they shared their emotions or what the details of their experience were had no contribution. In other words, Zech & Rimé (2005) showed that whether or not one shared their emotions played no part in decreasing negative emotion.

Other studies have exhibited the same opinion. Finkenauer & Rimé (1998) have conducted a study that inquires into emotional episodes that were either shared or not shared with others. By

comparing the two, they found that there was no significant difference in the intensity of an evoked emotion when recalling either. Rimé et al. (1991) and Stroebe, Stroebe, Schut, Zech, & van den Bout (2002) also reported that there is no relationship between social sharing of emotion and recovering from an emotional state.

So why doesn't social sharing contribute to recovering from negative emotions? Rimé (2007) has given a theoretical model for this (Figure 1). First, he purports that a negative emotional experience has a psychological effect from varying aspects, including motivational (frustration from not being able to achieve a goal), emotional (strong social desire and venting of emotion), cognitive (changing of schema and enforcement of unification), symbolic (enforcement of change of view in response to various things), action (suppression of action due to feeling helpless), social (desire for social approval and validation), self (reduced self-esteem), and memory (re-experiencing incidents). Either of these is considered to be unpleasant for someone who has had an emotional experience.

At the same time, Rimé (2007) contends that people also desire to regulate the various influences that come from these negative emotions. The regulation need is categorized between three needs, including 1) the desire for love, acceptance, social support, and approval (socio-affective needs), 2) the desire for concrete support, attention to one's surroundings, and regulation of one's own actions (action needs), and 3) the desire to reorganize objectives, revise schemas, re-evaluate incidents, and reconstruct meaning (cognitive needs). Reducing the negative emotions that occur due to an incident means that cognitive needs are being fulfilled. That is to say, unless cognitive needs are fulfilled, negative emotions won't decline and will continue to repeatedly enter one's conscious (see also Rimé, 2009). The importance of this cognitive reappraisal in controlling emotions has attracted attention in recent years in fields of study concerning the of emotions (e.g. Garnefski & Kraaij, 2007).

Figure 1. Theoretical model of regulation needs from negative emotional experience
Rimé, 2007.

In addition, Rimé (2007) conducted a series of studies which looked at what motivates people to share socially in order to see if these desires are being fulfilled in every day social settings. These studies looked into how subjects were motivated to share by having them recall emotional experiences which they had shared with others and indicate what motivated them to share their story. Through the study, Rimé (2007) asserts that first of all, social sharing allows people to obtain various reactions and support from the listener, which easily satisfies our socio-affective needs. Second, however, he argues that there are no motivations among these that satisfy our cognitive needs, and that even when we share out negative emotions socially in our general personal relationships, this sharing is not done based on our cognitive needs and therefore does not satisfy them. Social sharing of emotions thus is said to not contribute to reducing negative emotions.

Based on this theory by Rimé (2007), we consider that perhaps sharing our negative emotions with others, including anger on the Internet, does not reduce those emotions. Endo & Fuji (2015) focused on this and held a web survey to see the effect that social sharing of negative emotions on the Internet has. Their findings demonstrated that while negative emotions such as anger, anxiety, and depression that we evoke in our daily lives

push us to share them on the Internet, this social sharing does not reduce them, but instead maintains them. Fuji & Endo (2015) also considered what needs drive us to share negative emotions on the Internet and found that it is primarily our socio-affective needs and action needs, while our cognitive needs are ignored. Also, sharing of negative emotional episodes is more likely to be done immediately on the Internet than face-to-face (Endo & Fuji, 2015), as well as likely to be done without much cognitive processing or deliberation. Thus, social sharing on the Internet is hard to promote cognitive reappraisal in response to incidents and does not help reduce negative emotions. In addition, as previously mentioned, social sharing of emotion itself revitalizes emotions related to these incidents, which tells us all the more that negative emotions are difficult to reduce.

It is also understood that when negative emotions are shared, this also evokes largely negative emotion from the listener and encourages them to also share negative emotions with others (secondary social sharing; Christophe & Rimé, 1997). Specifically on the Internet, since it is easy to take something said by someone else and share it with others by either forwarding, quoting, or retweeting others comments, this secondary social sharing is easier to carry out.

Supporting this is a survey study conducted in China which targeted social networking services. Roughly 70 million posts made by the 200,000 users on Weibo, which is like China's version of Twitter, were collected and analyzed over a span of six months. Results showed that emotions of anger were more likely to be spread from user to user than emotions of happiness. Users connected with those that had submitted an angry posts also became angered and made their own angry submission (Fan, Zhao, Chen, & Xu, 2013).

To put it simply, an individual's anger is not reduced by being shared with others through the Internet, but instead ends up dragging others in and creates a large outpouring. Social sharing of emotion through the Internet does not reduce anger emotions for neither the individual who shared nor for those that it was shared with, and instead gives them an opportunity to spread anger.

EFFECTIVE WAY TO REGULATE ANGER EMOTION

This also poses the following questions: what can we do to reduce our anger? What do we need to do in order to not hold onto this anger?

A vital lead in considering this issue is a study done by Endo & Yukawa (2011, 2012) concerning the process of maintaining anger. While anger is easily experienced in our daily lives, it is an emotion that is short term and vanishes quickly. However, Endo & Yukawa (2012) conducted a study and found that over half of the respondents still were maintaining that anger over two weeks later. Based on this, Endo & Yukawa (2012) analyzed the factors that cause this anger and found that it being maintained is due to rumination repetitive thoughts about the incident that caused their anger and intrusive thoughts unwelcome involuntary thought, image, or unpleasant idea relating to an incident. In addition, these thoughts were demonstrated to be a result of the feeling that no solution regarding an incident can be found, causing unintegration with one's intentions, or an incident still threatening someone, leaving them unable to accept it. In brief, as long as this sense of unintegration of thought remains, anger will continue to be maintained due to continued rumination and intrusive thinking (Figure 2).

What does this mean? Normally, when people are feeling angry or stressed, they will first share what they are feeling with others or avert their attention elsewhere and attempt to turn their mood

Figure 2. The process of maintaining anger
Endo & Yukawa, 2012.

around. But these actions do nothing more than attempt to deal with the emotion that is caused by an incident and does not reduce the sense of unintegration of thought which is at the foundation of the incident. The emotion of anger thus continues to be maintained. In fact, Endo & Yukawa (2012) report that through avoidance behavior where we attempt to forget these incidents, we instead end up holding onto our emotions of anger. They suggest that in order to be released from this anger, people must confront these incidents, re-evaluate their significance (Rimé, 2007) and come to resolve and accept them through their own understanding.

In support of this, Endo (2009) conducted a further experimental study of expressive writing of anger emotion. This experiment asked participants to recall and write down experiences which they still presently felt stressed about due to anger deriving from past experiences. One week later, these participants were randomly divided among the following four conditions to tackle the issue: 1) that they verbalize and continue to note everything including the details and facts of the incident and their feelings, 2) that they continue taking notes by focusing on the emotions that they felt from the incident, 3) that they continue making notes by only focusing on the details and facts of the incident, and 4) that they continue to take notes concerning details that have no relation with the incident. Participants in each group were instructed to focus on tackling their tasks for three days straight.

In a span of one week, two weeks, and one month following these tasks, measurements continued to be taken concerning to what extent the participants still felt anger in response to their incidents. Results of this study proved very interesting. Among the four conditions, participants under the condition that they confront the incident which made them angry and verbalize it without making room for any objective facts or subjective emotions were shown to have the most reduced anger. In addition, participants under this condition had the most significantly improved score of the extent to which they felt clear about their

incident in terms of their thoughts and emotions. Conversely, those in the control group which did not confront their incidents showed no such results, nor was their anger reduced. We therefore find that Endo's (2009) experiments show that confronting an incident and resolving it through finding your own meaning for it plays an essential role in reducing anger.

FUTURE DIRECTIONS

Based on these study results, let us re-examine the act of expressing anger and sharing it on the Internet. The majority of anger expressed on the Internet for the purpose of sharing it with others is written in extremely short and fragmented writing. At the very least, communication which describes both one's subjective emotions and the objective facts in detail and is mutually shared is a rare occurrence. It is plausible that this trend has become more evident due to the appearance of social networking services that allow real-time communication, such as Twitter and Facebook. Thus, we presume from study findings concerning the regulation of anger emotions that the expression and sharing of anger on the Internet is difficult to link to the reduction of and recovery from angry emotions.

In summarizing our arguments, it would be appropriate to consider that expressing and sharing anger on the Internet cannot be expected to reduce anger emotions. Further social sharing also occurs through the evoking of anger by the listener who has been shared these emotions. In this way, anger is shared which is then maintained without being reduced, and the process repeats where this causes further sharing, which leads to a large outpour of flaming on the Internet.

In order to resist this outpour, Rimé (2007, 2009) suggests that we must do a cognitive reappraisal of the incidents that cause these emotions from a new perspective, which will lead to our own resolution and settlement (Endo & Yukawa, 2012). Only then will anger be reduced. For this

purpose, it is essential to take the time to refer to the emotions which we have experienced and the facts and put them into words (Endo, 2009). However, while such communication does not generally occur due to such media tending to focus on real-time interaction, it is deeply rooted to the background of this problem. Flaming on the Internet is not only bound to happen, but is an inevitable phenomenon. This is something that we must bear in mind.

CONCLUSION

The society in which we live today allows us to use the Internet as a means of expressing and sharing out anger. To put it another way, it has given us a new means for controlling the various anger we experience in our daily lives. However, questions still remain concerning the effective use of this new method for our benefit. What we need in order to calm our emotions through our own submissions and comments and prevent a spark that ignites large-scale flaming on the Internet is perhaps a calmness like that of water, to not be influenced by the characteristics of the media, and instead confront our emotions and ourselves and put our thoughts into words without making room for emotions and facts.

KEY TERMS AND DEFINITIONS

Cyber Cascade: A form of group-polarization on Internet.

Expressive Writing: Writing about past emotional experiences, including one's thoughts, feeling, and perceived facts.

Flaming: Large-scaled and offensive posting behaviors on the Internet.

Sense of Unintegration of Thoughts: The states when people could not integrate their thoughts by unacceptable events or unattained goals (see also Endo & Yukawa, 2012).

Social Sharing of Emotion: Communications about the emotional experiences in socially-shared language by the person who experienced them to other people.

W

Determine Democracy in Web Design

Rowena Li

Bayside High School Library, USA

INTRODUCTION

Surveys are the traditional and most widely used research instrument for measuring democracy. It is often used to measure the progress and decline of freedom and democracy in political rights and civil liberties experienced by individuals. As the Internet has become one of the most important vehicles of communication, and websites one of the most popular channels for information dissemination, a question has often been asked: in what way, if any, does a website, especially its homepage, carry its country's cultural traits and represent its nation's democracy level?

Evidently, web interface design reflects not only the linguistic aspects of a nation, but also its cultural characteristics, such as values, norms, and ethics. When we examine a country's cultural and social attributes represented on the web, one of the most important areas to consider is a country's democracy level, since power and authority create a special social structure for a society's culture.

Hofstede (1980) defined five primary cultural dimensions for measuring cultural differences. Power distance became the first dimension. Subsequently, Marcus (2005) and Marcus and Gould (2000) extended Hofstede's cultural theory to web interface design by identifying online indicators for the five cultural dimensions. Power distance received seven cultural indicators. These seven indicators, as well as three others (Gould, Zakaria, & Yusof, 2000; Singh, Zhao, & Hu, 2003, 2005), were statistically analyzed and validated in Li's (2009) study. Li concluded that special title, monumental building, authority figure, symbol of nationalism or religion, link to information about the leaders of the organization, information arranged according to management hierarchy, and

symmetric layout are valid indicators for measuring democracy on web interface design.

However, how exactly can web interface design be measured to detect a nation's democracy level with these seven indicators?

This article serves as an introduction to apply these seven indicators in examining democracy on web interface design. It introduces a new measuring instrument to assist in determining a nation's democracy level, so that democracy can be measured not only by traditional methods (surveys, case studies, questionnaires, interviews, and observations), but also through the study of web interface design. As a result, it extends cultural and political studies into the fields of human-computer interaction and user interface design.

BACKGROUND

Democracy and Its Measures

Over the years, the concept of democracy has been defined and redefined many times. For a long period of time, democracy has been associated with the demand of political and social equality (Laski, 1931). Some definitions for democracy place more emphasis on elections, examining voter participations and equal voting rights (Dahl, 1956; Lipset, 1963); others on the existence of political liberties (Lenski, 1966). Bollen (1980) defines democracy as "the extent to which the political power of the elite is minimized and that of the nonelite is maximized" (p.372). He argues that democracy should not be measured by voter participation, political stability, or multiparty political system, but by political rights and political liberties.

DOI: 10.4018/978-1-5225-2255-3.ch692

A growing number of studies concentrated on democracy measures and indices have been proposed and evaluated. First of all, whether democracy should be measured on a dichotomy approach (Lipset, 1959; Przeworski et al., 2000) or on a continuous scale (Bollen, 2009; Cutright, 1963) has been a major debate. Bollen (1990) believes democracy is continuous and should be evaluated in degrees. Although Bollen provided democracy indices for more than 100 countries, his studies only cover the years of 1960, 1965, and 1980 (Bollen, 1980, 1993). The Polity IV Democracy Scale, however, covers the years from 1800 to 2010 and “examines concomitant qualities of democratic and autocratic authority in governing institutions” (Marshall & Jaggers, 2012). It places a country’s democratic values on a 21-point scale. Freedom House Index of Political Freedom also places a country’s democracy on an ordinal scale. Freedom is measured by the progress and decline of freedom and democracy in political rights and civil liberties experienced by individuals. Each country is classified by the status of Free (Level 1.0 to 2.5), Partly Free (Level 3.0 to 5.0), or Not Free (Level 5.5 to 7.0) (Freedom House, 2015). Since its publication in 1972, this freedom rating remains as the standard in trans-national democracy evaluations (McClintock & Lebovic, 2006). Together with Polity scheme, it has become one of the two most widely used measures for democracy across countries (Foweraker & Krznaric, 2002).

Cultural Dimensions

In recent years, an increasing number of studies have focused on defining cultural dimensions. Hofstede’s (2001) five cultural dimensions have become the most quoted in cross-cultural studies and have been applied to a variety of research fields. After conducting two large surveys with 116,000 questionnaires, Hofstede concluded that four cultural dimensions (power distance, collectivism vs. individualism, masculinity vs. femininity, and uncertainty avoidance) can be used to measure cultural differences. The fifth cultural

dimension, long-term vs. short-term orientation, was added in 1991. In 2010, based on Michael Minkov’s analysis of the World Values Survey data for 93 countries, the sixth cultural dimension, indulgence vs. restraint, was included.

Hofstede’s cultural dimensions have been used to examine the impact of cultural differences of Asian-Americans on marketing strategies (Rallapalli & Montgomery, 2015), tax compliance (Putnam, Abdelfattah, Bagchi, & Braun, 2016), and market reception on capital structure (Arosa, Richie, & Schuhmann, 2015). The reliability of Hofstede’s cultural dimension was also validated in Bakir’s study (Bakir et al., 2015). Marcus’s study went further and made great contributions to cross-cultural study by applying Hofstede’s cultural dimension theory to web interface design (Marcus, 2005; Marcus & Gould, 2000). Marcus (2005) mapped Hofstede’s five cultural dimensions to user interface components and defined cultural indicators for each. Marcus and Gould (2000) also pointed out that power distance may influence several aspects of user-interface design, such as symmetric layout, information highly structured, hierarchies in mental model, nationalism or religion, focus on authority, official stamp, restricted security to access, and restricted managerial sections. At the same time, Gould, Zakaria, and Yusof (2000) examined three Malaysian and three US websites and concluded that prominent organizational charts, special title on members of the organization, and information arranged according to the management hierarchy are strong power distance indicators. Subsequently, Singh’s (Singh, Kumar, & Baack, 2005; Singh, Zhao, & Hu, 2003, 2005) studies also applied Hofstede’s cultural dimension theory to web content. They conducted considerable amount of scientific research to systematically validate Marcus and Gould’s framework in measuring cultural adaptation on the web. In their studies, six indicators were singled out as indicators for power distance.

Callahan (2007) examined cultural similarities and differences in terms of webpage organizations

and graphic designs. Her study found that cultural differences exist across countries and significant statistical correlations were found for the dimensions of power distance and individualism/collectivism between Hofstede's cultural dimension scores and the frequency counts of web indicators. Recently, while analyzing cultural elements in English-language and Chinese-language website designs, Chang (2011) found that cultural differences exist in power distance, uncertainty avoidance, individualism/collectivism, and long-term/short-term dimensions. Hsieh (2014) measured effects of cultural preferences on the use of web interface design and concluded that proper use of cultural elements on web interface design can promote the effectiveness of web communication.

Democracy and Web Interface Design

Built on previous studies, Li (2009) focused on statistical validation of national political freedom (democracy) indicators. Two coders performed content analysis on 156 college/university websites selected from 39 countries. The results indicated that six out of the ten proposed indicators could be used to measure a country's democracy on web interface design. They are, special title conferred on members of the organization, monumental building, authority figure, symbol of nationalism or religion, link to information about the leaders of the organization, and information arranged according to the management hierarchy. The seventh indicator, symmetric layout, demonstrated a negative correlation between the freedom level and the web representation of power distance.

Later on, Li (2010) used these seven indicators to determine if any differences exist between government-based websites and business-oriented websites in representing national political freedom. The result indicated that great differences exist in web interface design, which in turn reflects the national political freedom. The research concluded that web interface design correlates with a country's democracy level and government-based

websites embody more of a nation's authority and supremacy than business-oriented websites do.

Recently, Li (2014) used these seven democracy indicators in investigating the influence of geospatial factors on democracy and whether these associations are represented on web interface design. She concluded that democracy correlates positively with annual precipitation and latitude, but negatively with land boundaries and annual temperature. After examining 130 university/college websites collected from 65 countries, the study concluded that these four geospatial variables correlate with democracy represented on web interface design in the same manner, although these associations were not statistically significant. The study further suggested that the four geospatial factors be considered together as dependent variables to predict democracy more accurately.

MEASURING DEMOCRACY ON WEB INTERFACE DESIGN

As indicated in Li's (2009) study, democracy might be detected and measured not only in forms of surveys and questionnaires, but also through web interface design. Seven variables have been statistically verified in her study, which might be used as democracy indicators. They are:

1. Symmetric layout
2. Special title conferred on members of the organization
3. Monumental building
4. Authority figure
5. Symbol of nationalism or religion
6. Link to information about the leaders of the organization
7. Information arranged according to the management hierarchy

A content analysis method can be used to collect data from websites. The analysis is to carry out mainly on homepage with extensions to the

Figure 1. Homepage of University of Gadarif in Sudan at <http://www.gaduniv.edu.sd>

second and third level web pages. The seven power distance indicators are to be evaluated on a 0 (not present) to 4 (present to the most extent) scale with a coding sheet (Appendix). With some of the websites in languages other than English, a native speaker or an online translation service, such as Google Translate, should be consulted. If a website is presented in both English and its native language, the coding should be done based on its native language, since culture elements are best presented in their native languages.

In the course of selecting websites for sampling, it is necessary to consider the nature of the websites. College/university websites stand on a relatively neutral ground in providing information to their general audience in comparison with other types of websites, such as government-based or business-orientated websites. A government agency represents the power of its government and may reflect more of the authoritative aspects of an agency. On the other hand, the function of a

Table 1. Content analysis for University of Gadarif

Indicators	Coding
Symmetric layout (homepage): 75% symmetric	3
Monumental building: on the homepage as the focus	4
Symbol of nationalism/religion: on homepage and beyond	4
Link to information about the leaders: on every webpage	4

Authority figure: One on the homepage	3
Special title: on none of the webpages	0

business website is to introduce its products and service to customers and may target specific constituencies, so that localization may play a part in web interface design. College/university websites, on the other hand, target the same constituencies: future students, current students, visitors, faculty and staff, and alumni and donors both nationally and internationally. Therefore, both globalization and localization have to be weighted in consideration of their web interface design. With further consideration, museum websites, post office websites, and news/media websites might share the same neutral stand and achieve the same research results as college/university websites. Following are examples of sampling and coding two college/university websites in measuring democracy.

University of Gadarif from Sudan at <http://www.gaduniv.edu.sd> (Figure 1), for example, scored comparatively high on its coding sheet (22 points, Table 1). It features a 75% symmetric homepage (scored 3) with a monumental building on its homepage as a focus (scored 4). The symmetric feature is evaluated by comparing the left half with the right half of the webpage and the percentile is calculated by setting up visual horizontal lines to the webpage in four quarters. Neither left menu bar nor right menu bar is considered within the parameter when calculating the symmetric layout. The second indicator,

monumental building, is coded according to the webpage level on which a monumental building is displayed (homepage, 2nd level webpage, and/or 3rd level webpage), and whether it is the focus of the webpage or is only a background in a picture. Symbol of nationalism includes any national flags and/or country maps appeared on the website. Religious remarks, pictures, paintings, and web links to external religious websites are considered as symbols of religion. The basic coding criterion for this indicator is focused on the website level on which the symbol appears. For this website, a symbol of religion (“In the name of the God the Merciful”) is found on the homepage and on Management Service page via University Administration link (scored 4). Information on organizational charts, titles and ranks of the administrators is another indicator for democracy. It aims to find out the emphasis the web designers (or rather the administrators) place on the leaders (or administrators themselves) according to the location and the transparency of the information. It is believed that the navigation theme is achieved through the proper arrangement of the links on and between webpages. The information placed on the homepage is usually the most important of all. This is examined horizontally (the arrangement of the administration information on the navigation bar) and vertically (the website level is it placed on). The indicator, information arranged according to management hierarchy, is coded to examine the link arrangement on the navigation bar of the homepage. Navigation bars, in most cases, are place on the left/right side, at the top and/or at the bottom of a webpage. Sometimes, two navigation bars appear on the same page. Since the vertical navigation bar bear the same weight in importance as the horizontal navigation bar, the two bars weight the same in the coding theme. Generally, links on a navigation bar are arranged according to their importance from left to right or from top to bottom, except websites in languages written from right to left, such as Arabic. We might find out how important the web designers (or the administrators) view information on leaders

by examining the location of the Administration link on the navigation bar on the homepage. If the Administration link is not presented directly on the homepage, any link providing information on administrators or any link leading to administration is considered as the link to be examined for this purpose. Generally, Home link points back to the homepage and is placed as the first on the navigation bar. It is simply a navigation tool instead of an authoritative indicator. Therefore, it is not counted as one of the links displayed before the Administration link. On this website, the first link from the left - University Administration is the link to information about the leaders (scored 4) and is displayed on every page (scored 4). The indicator, authority figures, should be evaluated by the frequency of its appearance and the webpage level on which it is displayed. Authority figures include administrators and any prominent visitors. These authority figures can usually be found on the homepage, in News and/or Administration sections. They can also be found in Introduction section, under History link, which introduces former administrators of the organization. For University of Gadarif website, one authority figure is found on the homepage and again on a 3rd level page (scored 3). A special title placed in front of a person’s name usually shows a certain degree of respect and represents the importance of his/her

Table 2. Content analysis for University of Melbourne

Indicators	Coding
Symmetric layout (homepage): 75% symmetric	3
Monumental building: on none of the webpage	0
Symbol of nationalism/religion: on none of the webpage	0
Link to information about the leaders: on the 2nd level webpage and beyond	1
Information arranged according to the management hierarchy: On navigation bar, the Administration link is the 4th link or in the fourth group of links	1
Authority figure: on none of the webpage	0
Special title: on none of the webpage	0

Figure 2. Homepage of The University of Melbourne in Australia at <http://www.unimelb.edu.au>

social status. It can be of religion, political party, or social class, including but not limited to titles such as Honorable, H.E., His/Her Majesty, His/Her Excellency, His/Her Highness, Rev., Leader, etc. However, academic titles, such as Dr., President, and Dean, are not considered in this category. No special title appears on this homepage (scored 0).

On the other hand, University of Melbourne in Australia at <http://www.unimelb.edu.au> (Figure 2) scored only 5 in its web content analysis (Table 2). It has 75% symmetrical layout from left to right (scored 3). Only the top banner part is not quite symmetrical. Neither monumental buildings nor religious remarks/national flags are found on this website (scored 0 respectively). Link to information about leaders can be found via Contact Us link, through the links of About the University, Governance, and About Academic Board (scored 1 for the 2nd level webpage and beyond category). For information arranged according to the management hierarchy, Contact Us link is the 7th link on the homepage (scored 1). Neither authority figure nor special title is found on University of Melbourne website (scored 0 respectively).

The examples above suggest that the website of University of Melbourne in Australia shows more democracy than that of University of Gadarif in Sudan does. This result is consistent with the freedom ratings provided by Freedom House for 2012 at <http://bit.ly/zA5MaG>, which indicates that Australia is in the free-country group with its freedom level as 1 (1 is the most free and 7 the least free), while Sudan is in the not-free-country group with its freedom level as 7. This shows that the democracy levels detected from these two websites correlate with the freedom levels of their corresponding countries generated from surveys and questionnaires conducted by Freedom House. However, it is still too early to conclude that democracy measure for each website reflects its country's democracy level. Li indicated in her studies (2009, 2010) that the medians of the total scores for the three freedom groups did not spread out as they should and most of their inter quartile ranges overlapped with each other, although the means of the total scores for the three freedom group were statistically significant. This indicates some of the websites in the lower

quartile of free-country group scored very close to some of the websites in the upper quartile of partly-free-country group. As a result, it would be a challenge to draw a scientific conclusion of a country's democracy level based on the democracy measures of only one website. Therefore, it is necessary to increase the sample size to at least 10% of the population in order to get an accurate democracy level assessment for a country.

FUTURE RESEARCH DIRECTIONS

With technology transformation, the diffusion of innovations, and globalization and localization of the web, measuring democracy on web interface design will become an alternative assessment instrument in detecting democracy along with surveys, questionnaires, case studies, and interviews. As we have introduced the method and identified the indicators of measuring democracy on web interface design, web designer will be more aware of democracy issues in designing culturally adapted websites for international users.

Future study may focus on the evaluation of different website sectors in measuring democracy. These website sectors may include but not limited to college/university websites, news/media websites, entertainment websites, sports websites, postal office websites, museum websites, and so on. In this way, a new framework for measuring democracy on web interface design will be established.

CONCLUSION

This article has demonstrated a new approach to assess democracy on web interface design. It has introduced seven democracy indicators, which can be used to measure a country's democracy level through web interface design. Examples are given with illustrations to demonstrate the higher and lower ends. Detailed explanations of the essential elements to look for in the examination process are accompanied with each indicator. This approach

has been used in two recent studies to evaluate democracy on web interface design. Li (2010) used this content analysis approach and coded 312 government and business websites. The results then underwent two-way analysis of variance to examine if any statistical significance exists among the three freedom groups defined by Freedom House Index of Political Freedom and also between the two different types of websites. With this measuring approach, Li's study concludes that web interface design correlates with a country's political freedom level and government-based websites embody more of a nation's authority and supremacy than business-oriented websites do.

This measuring approach was once again used in the most recent study. Li (2014) collected data from 130 college/university websites selected from 65 countries using this coding sheet and conducted both linear and multiple regression analyses. The study concludes that democracy correlates positively with annual precipitation and latitude, but negatively with land boundaries and annual average temperature.

Since local websites embed more cultural values and are culturally sensitive, this new approach provides a better understanding for those who study the essence of cross-cultural interface design. It also helps researchers gain insights into the cultural characteristics of a nation. Furthermore, it has increased the awareness of cultural elements represented on web interface design in a way that general web users understand not only their own cultures, but other cultures as well. In addition, these democracy indicators will be an asset in investigating the impact of localization on web interface design by comparing an organization's local website targeting national audience with its mirror website designed for its international audience.

In general, measuring democracy on web interface design opens up a new perspective in the study of democracy. Sociologists, anthropologists, and information scientists will find this approach helpful in assessing democracy and promoting understanding of different cultures.

KEY TERMS AND DEFINITIONS

Collectivism vs. Individualism: Measures the relationship among individuals. In an individualistic culture, individuals value more on individualism; while in a collectivist culture, individuals view more on community and society.

Culture: A set of values, norms, and ethics shared by a group of people. It distinguishes one group from another.

Indulgence vs. Restraint: Measures the gratification for enjoyment and fun. Indulgence indicates the degree at which a society allows for relatively free gratification of basic and natural human drives related to enjoying life and having fun, while restraint stands for the degree of a society that suppresses gratification of needs and regulates it by means of strict social norms.

Long-Term vs. Short-Term Orientation:

Measures the tendency of perseverance or quick results. Societies with a long-term orientation show a strong tendency to invest and thriftiness to achieve long-term results, while societies with a short-term orientation have great respect for traditions and tend to achieve quick results.

Masculinity vs. Femininity: Measures the degree to which a culture views its gender roles.

Masculine cultures: tend to view males as tough conquerors and females as tender homemakers, while feminine cultures tend to reduce these gender differences.

Power Distance: Measures the degree of equality or inequality between people in a society.

Uncertainty Avoidance: Measures the extent people feel about uncertain or ambiguous situations.

Discussion Processes in Online Forums

Gaowei Chen

The University of Hong Kong, Hong Kong

Ming M Chiu

The Education University of Hong Kong, Hong Kong

INTRODUCTION

Using online discussions to facilitate learning is a major issue in information science and technology, especially with the increasing number of massively open, online courses (MOOCs). Online discussions involve a group of participants exchanging ideas by posting messages on an electronic medium (e.g., discussion forum, knowledge building environment). Due to its information transparency, communication flexibility and opportunities for reflection, online discussions in both independent forums and forums linked to school courses offer students additional opportunities for information processing, higher order thinking and learning (Chen, Chiu, & Wang, 2012a, 2012b; Gillani & Eynon, 2014; Qiu & McDougall, 2013).

However, an online discussion forum does not necessarily guarantee engagement, effective interactions or substantial learning (Hew & Cheung, 2014). For instance, despite the widespread use of MOOC forums, often only a small proportion of the students are active participants (Onah, Sinclair, & Boyatt, 2014).

This article discusses the advantages and disadvantages that online discussions offer compared to face-to-face discussions. Specifically, individual characteristics and message attributes can influence participants' thinking and social relationships (Chen et al., 2012a, 2012b). By understanding the discussion processes through which students create new ideas and develop social relationships in online forums, designers can improve online forum interfaces. Likewise, educators can capitalize on this information to

help students participate, cooperate and learn in online forums more effectively.

BACKGROUND

While online discussions have several advantages over face-to-face discussions, they also have some drawbacks. Online discussions' advantages include information transparency, communication flexibility and reflection opportunities. As online messages are explicit, relatively permanent and organized, they are more transparent than face-to-face talk. Online messages are written explicitly and stored, so group members and teachers/facilitators can access them later. Furthermore, authors can organize online discussion messages to highlight their relationships to other messages by responding along a specific thread or via quotes of previous messages (Chiu & Chen, 2013). The interface designs of some online discussion forums constrain each message to respond to a single previous message, which helps establish clear connections and avoid ambiguous relationships among messages. Readers who heed these explicit relationships can read the related messages in the authors' preferred sequence, which can facilitate their understanding of the messages' content.

As a result of their greater permanence, online discussions offer greater communication flexibility across time and space compared to face-to-face discussions. Face-to-face discussants must be in the same place at the same time to engage in a shared conversation. In contrast, synchronous online discussants can communicate with one an-

other from any location. In asynchronous forums, participants can review the relevant information or post messages at any time from any location.

Moreover, the greater permanence of online discussions also allows participants to take more time to reflect before responding, in comparison to face-to-face discussions, especially during asynchronous discussions (Hew, Cheung, & Ng, 2010). During face-to-face discussions, people respond in real time to one another, so they are less likely to spend much time editing their responses. In contrast, posting asynchronous, online discussion messages on a permanent online forum provides convenient access to participants, so they can spend minutes, hours, even days gathering more information from other sources, contemplating their relationships, and evaluating competing claims and justifications before writing a suitable response.

Online discussions also have some disadvantages compared to face-to-face discussions. For example, face-to-face discussion participants can use nonverbal facial expressions and social cues to clarify and reinforce their meaning. In contrast, online discussion participants cannot use them, which can lead to misunderstandings among participants (Walther, Loh, & Granka, 2005). Also, while multi-threaded discussions allow greater time flexibility, their demands are also less immediate. As these students do not need to respond immediately, they are more likely to ignore the messages and not respond at all (Hewitt, 2005; Thomas, 2002). Instead, they may initiate off-topic discussions (Wu & Hou, 2015). As participants can respond later, the group often requires more time to make group decisions, which can reduce their efficiency (Baltes, Dickson, Sherman, Bauer, & LaGanke, 2002).

Online discussion forums can be independent or linked to school courses. An independent academic forum is a bulletin board on a specific subject (e.g., high school geometry) but not related to any class or school. In such forums, peers communicate with one another as they wish, without instructor moderation or inference (Chen, 2004;

Chen & Chiu, 2008). In a course-related forum (e.g., a MOOC) however, an instructor may structure, scaffold, or moderate the discussions (Coll, Rochera, & de Gispert, 2014; Park et al., 2015).

ONLINE DISCUSSION PROCESSES

Like face-to-face discussions, online discussions include both problem content and social relations (Chiu, 2008). This section explicates the processes by which online discussants create correct, new ideas (micro-creativity) and develop social relationships. First, a theoretical framework characterizes online discussions at the message level, including a message's content and author. Then, it shows how specific message attributes and individual characteristics influence participants' micro-creativity and use of social cues during online discussions. By understanding students' micro-creativity and uses of social cues during online discussions, educators can help students engage in beneficial discussion processes that improve cognitive outcomes and positive social relationships.

Characterizing Online Discussion Messages

An online discussion message can be characterized along four dimensions: knowledge content, social metacognition, social cues, and individual characteristics (See Table 1; Chen & Chiu, 2008; Chiu & Chen, 2013; Hara, Bonk, & Angeli, 2000; Wong, Pursel, Divinsky, & Jansen, 2015).

As acquiring useful information is often a key discussion goal, the knowledge content dimension characterizes the information displayed regarding the focal topic: new ideas, old repetitions, and null content (Chiu, 2000). The validity of an idea is clear in some contexts (e.g., arithmetic), but not others (e.g., poetry). A justification provides evidence, an explanation or citation of an authority to support the validity of an idea (e.g., Neuman, Leibowitz, & Schwarz, 2000). Online discussants

Table 1. A framework characterizing online discussion messages

Dimension Categories	Description
Knowledge Content	
Correct, new idea (Micro-creativity)	An idea that is both correct (consistent with both subject content and problem constraints) and new relative to the discussion
Wrong, new idea	A new idea that is inconsistent with at least the subject content or problem constraint
Justification	An action that supports a new idea by linking it to data, using a warrant, or backing (Toulmin, 2003)
Repetition	An idea that has been mentioned earlier in the topic being discussed
No academic content	A message without any problem-related information (e.g., simple evaluations ["No"], simple questions ["What?"], or off-topic information ["Where are you from?"])
Social Metacognition	
Agree	Agree with a previous message
Disagree	Disagree with a previous message
Question	A query that expects a response
Command	A directive to demand/stop an action
Social Cues	
Positive	Words, symbol, or emoticon expressing a positive attitude or affective state toward others
Negative	Words, symbol, or emoticon expressing a negative attitude or affective state toward others
Individual Characteristics	
Masculine	A masculine participant, as indicated by nickname, photo, personal statement, etc.
Feminine	A feminine participant, as indicated by nickname, photo, personal statement, etc.
Past forum experience	The number of past messages posted by a participant
Topic initiator	A discussant who initiates the current topic

can monitor and try to control one another's actions (social metacognition, Chiu & Kuo, 2009). For example, online discussants can use evaluations (e.g., agree, disagree) to assess one another's ideas and identify flaws. Also, they can invite audience participation to varying degrees with an invitational form (e.g., question, command).

Discussions can contain positive or negative social cues. These include verbal or nonverbal actions in face-to-face discussions and words, symbols, or emoticons in written messages in online discussions (Derks, Bos, & von Grumbkow, 2007). Igniting emotional responses, social cues can help build up or tear down social relationships, along with the collaborative fabric of their discussion (Sproull & Kiesler, 1986; Swan & Shih, 2005).

Lastly, individual characteristics denote a message author's displayed identity. During online discussions, participants usually do not know one

another's actual individual characteristics. Instead, they often portray a public image by displaying information such as online gender or past forum experience. By initiating a topic or responding to one, they also announce their role.

Micro-Creativity Processes During Online Discussions

Micro-creativity is an expressed idea that is both correct (consistent with the problem situation and the subject content) and new relative to the topic discussion. Like face-to-face discussions, online discussions with greater micro-creativity are more likely to yield correct solutions to problems (e.g., Chiu, 2008). Hence, understanding micro-creativity processes can help educators improve online students' understanding, group problem solving and learning. Specifically, new

ideas and justifications (knowledge content), disagreements and questions (social metacognition) in recent messages and authors' individual characteristics can facilitate or hinder participants' micro-creativity (Chen et al., 2012a).

New Ideas and Justifications

As online discussants are often geographically and culturally diverse, they are more likely than face-to-face discussants to have diverse views and sources of knowledge (Swann, Kwan, Polzer, & Milton, 2003). Capitalizing on this diversity, heterogeneous participants can both generate diverse ideas and build on one another's micro-creativity through processes such as sparked ideas and jigsaw pieces (Paulus & Brown, 2003). One person's micro-creativity (e.g., a key word) might spark another person's micro-creativity by activating related concepts in his or her semantic network (Nijstad, Diehl, & Stroebe, 2003). For example, when responding to a micro-creative act, " $5 \times 9 = 5 \times (10 - 1)$ ", a participant might continue the thread and add another micro-creative act: " $5 \times (10 - 1) = 5 \times 10 - 5 \times 1 = 50 - 5 = 55$." Like fitting jigsaw pieces together, participants also can combine micro-creative acts into a new micro-creative act (Milliken, Bartel, & Kurtzberg, 2003). Hence, recent micro-creativity can increase subsequent micro-creativity.

A justification suggests that an idea is reasonable and hence, often enhances its perceived validity (e.g., Neuman et al., 2000). A justification can support an idea's validity by linking it to data, using a warrant, or supporting a warrant with backing (Toulmin, 2003). Furthermore, online discussants justify new ideas in explicit writing during online discussions, so they are more likely to recognize errors and specify relationships among ideas more precisely than during face-to-face discussions (Jonassen & Kwon, 2001). Hence, justifications can support the validity component of new ideas, identify errors, and clarify relationships to aid micro-creativity.

Disagreements and Questions

Unlike agreements, a disagreement tries to alter the discussion trajectory by identifying obstacles/flaws of the previous action or by developing alternatives. A respondent who recognizes a flaw or has a conflicting view of the previous message's understanding of terms, concepts, or schemas is likely to disagree with the previous message (Gunawardena, Lowe, & Anderson, 1997). To support his or her disagreement, the respondent might add a new idea. Or, other participants might address the disagreement with subsequent micro-creativity, according to socio-cognitive conflict theory (Buchs, Butera, Mugny, & Darnon, 2004; Piaget, 1985). In both cases, disagreements can aid micro-creativity, either immediately or in subsequent actions.

When a discussant has both supportive and conflicting information regarding a previous message, online discussants are more likely than face-to-face discussants to disagree. During a face-to-face discussion, participants often seek to enhance their relationship with other group members by agreeing while withholding the conflicting information (Chiu & Khoo, 2003). During an online discussion however, concerns about one's public self-image (face) are less salient (politeness theory; Brown & Levinson, 1987), so online discussants disagree more often than face-to-face discussants do (Lu, Chiu, & Law, 2011). As noted above, this disagreement can facilitate micro-creativity, either immediately or in subsequent messages (according to socio-cognitive conflict theory).

As in face-to-face discussions, questions during online discussions can facilitate discussions by inviting new ideas. When discussants recognize problematic ideas, they can ask questions to identify these knowledge gaps and elicit more information (e.g., "Could you explain the steps further?"). These questions can invite further elaborations, justifications, and micro-creativity. Furthermore, online discussants have a permanent

record of their discussion, no conversation turn structure, more time to find related information and more time for reflection, so online discussants are more likely than face-to-face discussants to reflect on a question, which can increase micro-creativity (Hara et al., 2000). Without a record to support their limited working memory, face-to-face discussants who cannot recall relevant information often ask other group members to review old information rather than create new information, resulting in less micro-creativity (Chiu, 2008). As face-to-face discussants wait their turn to respond to a question, they might forget their ideas or decline to share them if the topic has changed. In contrast, online discussants can write their new ideas at any time and attach their message to the relevant prior message.

Individual Characteristics

Gender differences in micro-creativity might be smaller in online discussions than in face-to-face discussions. As online discussants are less certain of one another's sex, their gender identities are less salient (Palomares, 2004). Also, as the anonymity of online discussions obscures individual differences, online discussants are more likely to perceive the group as an entity, thereby enhancing the salience of the shared social identity (social identity model of deindividuation effects; Postmes, Spears, & Lea, 1998). As a result, behaviors of males vs. females are less likely to differ in online discussions than face-to-face discussions.

Online discussants' past activities in online forums might facilitate their micro-creativity (Wong et al., 2015). Experienced participants with many past posts are more likely to carefully consider others' messages, use time to reflect, and search for more information, all of which might aid micro-creativity. Furthermore, experienced participants are less likely to be frustrated by technological barriers of online discussions, thereby asking fewer technology-related questions (e.g., "How do I type mathematical equations in this forum?"). This in turn allows them to invest more

time and effort in content-focused discussions, which can yield more micro-creativity.

In the forums where discussants respond to an initiator's questions, initiators often ignite discussion topics because they have knowledge gaps in the subject matter and seek to fill the gap by interacting with others (e.g., "Can you explain how to solve this problem?"). Hence, an initiator often shows less micro-creativity than the respondents during discussions.

The Processes of Using Social Cues During Online Discussions

Online discussants' use of social cues can reflect their social relationships. A social cue is a participant's expressed emotion or attitude toward others during a discussion. Specifically, positive social cues refer to a discussant's expression of positive affective states (e.g., "Oh, I get it now") or positive attitudes toward others (e.g., "Thanks for your explanation"). In contrast, negative social cues express negative affective states (e.g., "☹") or negative attitudes toward others (e.g., "No, I'm not, YOU are wrong!!!"; McKee, 2002). While positive social cues signal creation and maintenance of a mutually respectful, supportive, and encouraging climate that promotes positive social relationships and collaboration in the problem content space (Garrison, Anderson, & Archer, 2000), negative social cues often create a discouraging, aggressive or hostile environment that harms participants' social relationships and collaborative learning (Paulus & Roberts, 2006; Sproull & Kiesler, 1986); ritual insults are a notable exception (Progovac & Locke, 2009).

Agreements and Disagreements

When agreeing with a previous idea, online discussants who feel strongly about it might add affective words (e.g., "Aha, I agree with you") or emoticons (e.g., "Yes ☺"), which parallel smiling agreements in face-to-face discussions. In contrast, participants who agree but do not feel

strongly are less likely to post a message at all. By expressing an agreement with positive social cues, the respondent support the previous participant's face, enhance their common ground, and make the discussion more enjoyable, all of which promote positive social relationships (Vinagre, 2008).

When face-to-face discussants disagree with a previous idea, they often disagree politely with positive, verbal and non-verbal social cues to mitigate the threat to the speaker's face and show shared positioning (Brown & Levinson, 1987; Chiu & Khoo, 2003). The benefits of face-to-face polite disagreements are so strong that it is the accepted norm among peers; lack of redress during a face-to-face disagreement is noticeably rude and unacceptable (Holtgraves, 1997). During online discussions however, anonymity and reduced face concerns allow participants to disagree with one another more freely. Thus, online discussants are less likely to use positive social cues to soften or redress disagreements. Moreover, they often add negative social cues to disagree rudely due to the reduced normative constraints of online discussions (e.g., adding exclamation marks, "You made it too complicated!!!!").

New Ideas and Justifications

Online discussants are less likely to use social cues when providing new ideas and justifications. Unlike face-to-face discussions, online discussions lack nonverbal channels' rich interpersonal information (Derks et al., 2007). Furthermore, online discussants usually do not know each other, have weaker social commitments, and are separated by greater psychological distance (Chen & Chiu, 2008; Hiltz & Goldman, 2005). Due to narrowed social cue channels, reduced immediacy and weaker past relationships, online discussants are less likely to attend to others' social presence when sharing new ideas (Sproull & Kiesler, 1991). If participants focus more on problem content and less on social relationships, they are less likely to use social cues when contributing

new ideas. Furthermore, justifications facilitate calm reason-based communication (Chiu, 2008). When justifying new ideas, online discussants often focus on the problem content rather than on their social relationships, so social cues are less likely to accompany justifications.

Earlier Social Cues

While the effects of earlier social cues on subsequent social cues are similar in face-to-face and online discussions, their intensities differ. People tend to reciprocate positive social cues. According to social information processing theory, online discussants often spontaneously post positive social cues to develop positive and meaningful relationships (Vinagre, 2008). Likewise, negative social cues harming social relationships might elicit more negative social cues. For example, a negative social cue, "Can you be more WRONG?!" can threaten the face of the previous participant (Brown & Levinson, 1987). The previous participant can retaliate, with another rude, emotionally-loaded response, "Can you be more STUPID?!" to protect his or her face and attack the previous participant's face (Gottman & Krokoff, 1989). With less social presence in the online discussion environment, negative social cues occur more often there than in face-to-face discussions (cues-filtered-out perspective, Sproull & Kiesler, 1986).

Individual Characteristics

As with micro-creativity, social cue use differs less across gender in online discussions than face-to-face discussions. Initiating an online discussion topic often indicates both a knowledge gap in the subject and motivation to fill that gap by asking others. By using positive social cues and being polite, an initiator is more likely to receive satisfactory responses from others, especially in online discussions in which many messages receive no responses (Hewitt, 2005; Thomas, 2002).

RECOMMENDATIONS FOR TEACHERS AND FORUM DESIGNERS

This chapter highlights how new ideas, justifications, disagreements, and questions can affect micro-creativity and social cues during online discussions. To aid students' micro-creativity and social relationships, teachers can encourage them to prepare their messages carefully, brainstorm new ideas, justify them, and evaluate their ideas carefully (Chen et al., 2012a, 2012b). Meanwhile, forum designers can design the interactive environments that hinder the use of negative social cues (Chen et al., 2012b).

Unlike real-time face-to-face discussions, asynchronous online forums allow delayed responses, so teachers can encourage students to spend more time thinking about their messages, gathering more information, and polishing their messages, which can foster their micro-creativity. Students can brainstorm many ideas before writing out their justifications to choose the best ideas. As micro-creativity can foster subsequent micro-creativity, these micro-creativity chain reactions might be more likely to yield a solution. Meanwhile, students can consider whether they can justify their ideas, which would increase their likelihood of being correct. New ideas and justifications during online discussions reduce the likelihood of social cues, suggesting that when students are reasoning about the content, they can devote less effort to social cues. Hence, when students contribute new ideas and justifications, teachers need not be concerned about the absence of social cues and need not to try to promote them.

Negative social cues during disagreements can tear apart a group's cohesiveness, so teachers often worry about them. As negative social cues and disagreements often occur together in online forums, teachers can encourage students to evaluate one another's ideas slowly and carefully, thereby reducing impulsive, false disagreements that might yield negative social cues and face attacks. Furthermore, the prevalence of such dis-

agreements during online discussions suggests an important role for a teacher: encouraging positive social cues during disagreements to help save face and discouraging face attacks, especially with negative social cues (Savvidou, 2013).

As online discussants often use negative social cues when disagreeing, forum designers can create online discussion environments that hinder their use. For example, forum designers can offer fewer ready-to-use negative emoticons (e.g., emoticons expressing anger or attack) on the toolbar. Also, they can consider adding an automatic detection function to the forums, which would remind the participants to remove inappropriate emoticons/words before they post their messages. By doing so, online discussants might be less likely to use negative emoticons/words to express their impulsive negative feelings when disagreeing.

FUTURE RESEARCH DIRECTIONS

In addition to testing the validity of the above discussion processes, future research can investigate the impact of teacher messages on student messages in course-related forums and compare how students' cognitive and affective styles affect their responses to teachers' messages (Park et al., 2015; Wu & Hou, 2015). Future research can also explore how techniques such as visual analytics and intelligent support can be designed and used by teachers and students to facilitate their online discussion processes (Hsiao & Awasthi, 2015; Kumar & Kim, 2014). Addressing these questions can improve the understanding of students' discussion processes in online forums.

CONCLUSION

This article discusses the processes that influence online discussants' micro-creativity and use of social cues during their discussions. Specifically, new ideas and justifications, disagreements and questions in recent messages facilitate micro-

creativity during online discussions. New ideas and justifications are likely to reduce both positive and negative social cues during online discussions. While agreements facilitate positive social cues, disagreements facilitate negative social cues. Meanwhile, more experienced participants (who have more past posts) are likely to show micro-creativity. Topic initiators are less likely to show micro-creativity but more likely to display positive social cues. Together, these mechanisms show how messages in online discussions create a local context that influences participants' correct outcomes and social relationships.

KEY TERMS AND DEFINITIONS

Micro-Creativity: An idea that is both correct (consistent with both subject content and problem constraints) and new relative to a discussion.

Multi-Threaded Discussion: A discussion in which messages proceed along multiple threads.

Negative Social Cue: A discussant's expressed negative affective state or negative attitude toward others.

Online Discussion Message: The content that an online discussant posts at a time.

Online Discussion Topic: A topic or problem that initiates a discussion.

Online Discussion: A discussion in which a group of participants exchanging ideas by posting

messages on an electronic medium (e.g., online forum).

Positive Social Cue: A discussant's expressed positive affective state or positive attitude toward others.

Social Relationship: The relationship between two or more participants during an online discussion, as indicated by their use of social cues.

Topic Initiator: A discussant who initiates the current online discussion topic.

W

The Economics of Internetization

Constantine E. Passaris
University of New Brunswick, Canada

INTRODUCTION

Internetization is a new word and concept that has gained currency with the advent of the new global economy of the 21st century. Prior to the ascendance of Internetization economists had embraced the term globalization to describe the operational parameters of the new economy. The problem with the word globalization is that it is neither a new concept nor is it an appropriate descriptive for the contemporary transformational change precipitated by the spectacular technological inventions on the international economic landscape.

Globalization does not portray the enabling powers of contemporary technology. This electronic capacity has empowered the information technology revolution which is a defining feature of the new global economy. Globalization is a throwback to a previous age prior to electronic connectivity and with more limited means of information accessibility and rapid communication.

The new word, Internetization, describes more succinctly the transformative powers of the world-wide-web and the electronic information highway on the evolving dynamics of interconnectivity for the new global economy of the 21st century. Indeed, Internetization captures the pervasive influence of technological change and electronic innovations on the global economy and all aspects of human endeavour for our civil society in the 21st century.

BACKGROUND

Globalization is not a modern concept or a new theoretical construct. Indeed, it has been a constant feature of international economic outreach since

time immemorial. Globalization has evolved and mutated over the centuries to reflect the priorities and ambitions of different generations. The global outreach of nations for geopolitical, economic, military and trade benefits has transgressed the centuries and embraced almost every country in the world (Erllichman, 2013).

From time immemorial, the process of globalization has taken different forms and proceeded in different directions. Through the discovery and exploitation of new found lands, through the military conquest and annexation of adjacent territories and through the signing of contemporary multilateral free trade agreements, the process of globalization has been an uninterrupted continuum in the evolving history of humankind.

Examples of globalization in ancient history include the seafaring voyages of Odysseus recorded by Homer in *The Odyssey*. The Babylonian Empire that stretched over Mesopotamia in western Asia between the rivers Tigris and Euphrates from 1894 BC to 1595 BC, and again from 625 BC to 539 BC when its grasp reached as far as Palestine. The conquests of Alexander the Great (356 BC to 323 BC) forged an empire that included parts of Europe, Africa, and the Asian continent as far as India. In the late 3rd century BC, the Romans began their conquest of the Balkan Peninsula in search of iron, copper, precious metals, agricultural crops and slaves. This marked the beginning of the Roman Empire, which lasted from 27 BC until 476 AD, and blended unity and diversity across Sicily, Spain, Macedonia, Greece, Egypt, North Africa, Syria, parts of Asia Minor, Gaul and Britain. The Byzantine Empire lasted from 395 AD to 1453 AD and spanned the Middle East, North Africa and Spain. The British Empire from 1583 AD to 1931 AD included such a large collection

DOI: 10.4018/978-1-5225-2255-3.ch694

of countries around the world that it sparked the familiar phrase “the sun never sets on the British Empire” (Passaris, 2006a).

This short and selective geographical survey of the history of globalization attests to the permanence of humankind’s international ambitions. The steady progression of globalization has found expression in the geopolitical and economic ambitions of military, economic and political superpowers. Their globalization ambitions have been achieved by means of wars, mercantilism, colonization, political and economic supremacy, and more recently, through international economic liaisons and multilateral trade agreements.

NEW ECONOMY

The new global economy of the 21st century has transformed the economic, social, educational and political landscape in a profound and indelible manner. Never before in human history has the pace of structural change been more pervasive, rapid and global in its context.

The new economy has become a catalyst for geopolitical symbiosis, economic integration and financial interconnectedness. The new economy is composed of a trilogy of interactive forces that include globalization, trade liberalization and the information technology and communications revolution. Globalization has melted national borders and redefined economic policy. Free trade has enhanced economic integration and extended the economic architecture. The information and communications revolution has made geography and time irrelevant and enhanced the reach of economic parameters (Passaris, 2015).

The advent of the new economy has resulted in the fundamental restructuring of economic society. Electronic interconnectedness is the glue that holds the contemporary global economy together. The new economy is built on a culture of innovation and an emphasis on creativity. Indeed, the signature mark of the new global economy is new ideas, new technologies and new initiatives.

ECONOMIC GLOBALIZATION

A working definition of economic globalization in its contemporary form can be summarized as the global integration of economies through trade and investment flows as well as the internationalization of the production of goods and services. The economic profile of globalization includes the development of global corporations and global networks. It also includes the widespread internationalization of all forms of economic activity in production, marketing, consumption, capital, standards and tastes. Economic governance has resulted in a rapid growth in intra-firm and intra-network trade of components and sub-assemblies as well as finished products leading to a much higher level of specialization (Rodrik, 2008).

Globalization has become the catalyst for the re-orientation of large-scale production in high wage economies from economies of scale to economies of scope. It has contributed to the shortening of product cycles, placing a high premium on innovation, product quality and niche marketing. Globalization has also witnessed the rapid growth and diffusion of service and knowledge-intensive activities, for both products and processes (Huwart & Verdier, 2013).

The process of globalization has been driven by technological change and financial liberalization and sustained by an appreciation among policy makers that an open and rules-based international trading and financial system is essential to global economic progress (Stiglitz, 2008). The new economy has become truly global in scope and substance. The free flow of capital, labour, goods and services within free trade regions, the development of new financial instruments and institutions, instantaneous access to information and communication through the new digital networks, have created a fully integrated global economic system of tremendous scope and opportunity. Economic globalization has achieved a higher level of international economic interdependence and linkages than ever before. For example, the speed and rapidity of economic and financial

contamination across national borders during the 2008 financial crisis is a case in point.

TRADE LIBERALIZATION

The second axiom of the new economy is trade liberalization. The prevailing philosophy in favour of trade liberalization is based on the export led growth model which espouses the economic benefits of exports to the national economy in the form of employment creation, income generation and as a contributor to economic growth (Wacziarg & Welch, 2008).

In the contemporary context, most countries around the world have endorsed the principle and signed on to the potential economic rewards from global trade liberalization. The contemporary vision of the new global economy embraces the promotion of a free trade environment that encourages trade across national borders of goods and services, the legal transfer of intellectual property and the unregulated flow of financial capital. The economic benefits of this modern paradigm along with improvements in the international transportation network have resulted in the expansion of the range of tradable products and services and empowered the global integration of the domestic resources and the production capacity of national economies (Michael, 2009).

One of the most striking differences between the new economy and the one that preceded it is found in the magnitude and rapid movement of international capital flows. Capital account liberalization, the development of new financial instruments and the emergence of new digital technologies have created a fully integrated capital market of tremendous scope and composition. Indeed, a major force driving the growth of international trade and investment has been the liberalization of capital controls, exchange regulations and global financial transactions (Passaris, 2011a).

In short, both deregulation and technological innovation are driving the modern globalization process by tearing down the barriers that

have separated economic markets and reducing transportation and production costs. This has contributed to a greater willingness and ease to trade and invest in foreign countries.

INFORMATION TECHNOLOGY

Information and communication technologies play a central role in the new global economy of the 21st century. The information technology revolution has profoundly altered the structural parameters and the modus operandi of most national economies. More specifically, information and communications technologies have altered the production function, enhanced productivity growth, facilitated the collection of data, spearheaded the transmission of ideas and extended the reach of economic and social interactions. Scientific advances and technological breakthroughs have contributed to the success of the information and communication technology in effectively shrinking the time and distance that separate economic regions and international markets around the world.

The role of information and communications technology in the new economy has been pivotal. This is particularly true of the changing structure of international production. In this context, firms are integrating the production and marketing of goods and services across national borders. International economic transactions that were formerly conducted between independent entities are now being internalized within a single firm or multinational corporation. The new technological infrastructure has empowered services to be delinked from production and traded or performed remotely. In this contemporary venue the market for a growing number of internationally integrated but geographically dispersed business enterprises is global, rather than national or regional (Passaris, 2006a). Indeed, information and communications technologies have displaced the physical market with the virtual market of the Internet for business to business and business to consumer transactions.

At the very heart of the information and communications revolution is the vital process of the commercialization of scientific discoveries and new inventions. There is no denying that the road well-travelled from invention to innovation is long and fraught with many obstacles (Jones, 2009). It is not unusual for many inventions to be left behind because of obstacles in securing the necessary financial capital or adapting an invention to the economic realities of mass production. Indeed, an invention that is the product of a new idea, extensive research and a successful laboratory controlled experiment does not guarantee that it will result in the launch of an innovation. An idea for a new product, a better product or a new process that meets all its specifications as a blueprint and results in a successful invention in a controlled environment may turn out to be an unprofitable undertaking in the world of mass production and global competition. Furthermore, in this modern era individual inventors like Graham Bell, Thomas Edison and Guglielmo Marconi who endowed us with path breaking inventions practically single-handed, are few and far between. Inventions today are more likely to be the product of a team effort and a concerted research and development initiative of some government laboratory, academic institution or a major corporation.

Economists are divided into two schools of thought regarding the process that leads to inventions. The first school subscribes to the notion that inventions are an incremental and marginal process. The second school of thought argues that some inventions are the catalyst for abrupt structural change that permeates the economic landscape in a tidal wave of production realignments and technological clustering. Regardless of what school one subscribes to, there is no denying that the great inventions that took place during the industrial revolution between 1860 and 1900 had a profound impact on economic productivity and personal lifestyle. These inventions included electricity, the internal combustion engine, radio, the telephone, phonograph, motion pictures, the chemical and pharmaceutical indus-

tries, advances in entertainment, communications, urban sanitation and travel in the form of air and motor transportation. The information revolution has also triggered a new spurt of inventions with expansive structural changes and a cluster of innovations with a far reaching economic and social impact. The list of inventions ascribed to the information revolution is still in its infancy but already it includes such significant inventions as computers, the Internet and wireless telecommunications devices.

The role of innovation as a catalyst that drives the engine of economic growth is a fundamental postulate of the new global economy. Contemporary economies have recognized the important role of innovation in nation building and have devoted their resources and public policy focus towards supporting and enhancing the advancement of innovation. Accelerating the process of innovation is vital to ensuring that national economies create and sustain wealth in a swiftly changing global economy.

INTERNETIZATION

The ancient Greek philosopher Heraclitus observed that there is nothing permanent except change. In this regard, recent structural changes on the economic landscape and the collateral requirements for rapid economic recalibration are becoming essential prerequisites for successfully navigating the new global economy.

The shortcomings and limitations of the term globalization requires the introduction of a new word and a new conceptual framework. A new word that is an appropriate descriptor for the operational parameters of the new global economy of the 21st century. Indeed, the word globalization does not embrace the intricacies and nuances of the new world economic order. Furthermore, globalization does not project the extensive digitalization and the electronic connectivity that permeates the new global economy. The word Internetization is new to the economic

lexicon. It was coined for the singular purpose of replacing the word globalization. Internetization captures the importance of the electronic and digital transformation that has defined the new global economy and the pervasive influence of the World Wide Web and the information super highway on all aspects of human endeavour for our society in the 21st century. The transformation of globalization into Internetization was facilitated by the creation of a digital infrastructure that enabled global outreach through electronic connectivity.

The process of Internetization is not static. It is constantly evolving, mutating and transforming. The capacity for Internetization took a giant leap forward with the transformation of wired electronic technology into wireless devices. New technological frontiers have been reached through nanotechnology, Internet of Things, cloud computing and virtual networks.

The word Internetization has gained currency and visibility since it was first introduced into the economic lexicon during the first decade of the 21st century. It has become widely adopted by the academic community and has appeared in scholarly publications (Passaris, 2001; Passaris, 2006b; Kwan, 2011; Tan, 2013; Ankit, Khandelwal, Sinha and Alex, 2014; Iakobidze & Turashvili, 2014). Internetization has been used as a Twitter hashtag since 2009.

Internetization has precipitated a global communications network that connects billions of people to data, machines, computers and each other. The Internetization process has extended social contact, facilitated economic liaisons, enhanced the transmission of services, disseminated knowledge and ideas and truly made the world a global village. In essence, Internetization refers to how people, businesses and cultures have increased their capacity to interact on multiple levels through revolutionary advances in digital technology.

On the social front, Internetization has broken the ties of neighbourhood based on geographical proximity and replaced them with electronic communities. Similarly, family ties based on blood

relatives have been extended through the medium of the Internet and social media. This domain now includes a broader social community of likeminded people with similar interests who socialize on Facebook, Skype, LinkedIn, Instagram and Twitter. In consequence creating a new code of civil values and communications etiquette.

Internetization has had a significant influence on the scope and magnitude of the new global economy of the 21st century. Indeed, Internetization is the catalyst that binds and connects the three pillars of the new global economy and empowers the synergies that are the signature mark of the modern economic landscape. Internetization is a process that is empowered by the information and communications technology revolution in a borderless world with a tremendous capacity for virtual connectivity. In short, Internetization combines the modern version of globalization with the economic empowerment of the Internet.

All in all, Internetization covers more ground, has more contemporary descriptive features and is a more comprehensive concept than globalization for the new economic landscape. This is especially the case as an ever growing number of people from around the world use the Internet as a daily means of accessing new information resources, conducting more convenient financial transactions, experiencing new means of social interaction and indulging in instantaneous means of communication.

Hardly a day goes by when our individual and collective lives are not touched by some aspect of the information technology and communications revolution. From the way we shop, eat, dress, invest, travel, entertain ourselves, communicate with each other, access health care, or pay our bills. These are just a few of our routine daily functions that have been profoundly influenced by the process of Internetization. We shop on-line, we access government services on-line, we book our travel itinerary on-line, attend church services on-line, we pay our bills on-line, we read our newspapers on-line and we do our banking on-line. The electronic prefix that is appearing before an

increasing number of our daily interactions such as e-commerce, e-mail, e-learning, e-banking and e-government is a tangible expression of the pervasive influence of the information technology revolution and the Internet (Passaris, 2006b).

Governance and government services have experienced a foundational transformation as a result of Internetization. Public policy in particular has been subjected to a higher degree of transparency and accountability through the digitalization of government documents. Open government has become the new standard for modern governance (Passaris, 2011b). Furthermore, Internetization has facilitated the digital interface between the public and government services. This interface covers a broad range of services including accessing, completing and submitting forms and applications online, bidding for government contracts, acquiring motor vehicle licenses, filing income tax returns, the issuing of birth and death certificates, marriage licenses, applications for retirement benefits, filing copyright documents, applying for veterans benefits and a host of other public services.

The process of Internetization describes the role of modern technological enablers and the capacity of the Internet in empowering the new global economy of the 21st century. This has been achieved through the advent of computerization, the technology of instant communication, by extending the capacity of economic outreach and by enhancing the speed for completing financial transactions. In short, the word Internetization combines a more comprehensive dimension of the modern era of global outreach and the economic empowerment of the Internet.

Internetization has had a significant influence on the scope and magnitude of the new global economy of the 21st century. Electronic interconnectedness is the glue that holds the contemporary global economy together. The new economy is built on a culture of innovation and an emphasis on creativity. In effect, Internetization is a more comprehensive and contemporary descriptor of the new economic landscape. Particularly since

the public and private sectors, small, medium and large businesses, non-profit organizations and community associations rely on the Internet.

The information technology revolution has profoundly altered the structural parameters and modus operandi of most national economies. Internetization has become the catalyst and the engine that drives the information and communication revolution in the context of the new economy. This takes the form of the digitization of information and the creation of the information super highway. Furthermore, the industrial age created territorial communities whereas the information age is creating electronic communities.

Internetization is multifaceted and multidimensional. This has become abundantly clear in the contemporary knowledge driven economy. At the very heart of the information technology applications for the knowledge based sector is the widespread use of computers and robotics. A collateral benefit of this transformation has been the extraordinary scale of research and development in the quest for new applications for the advances in information and communications technology. This has triggered the phenomenal growth of the software industry and related business services. Indeed, the scale of investment in computerized equipment and in the telecommunications infrastructure is unprecedented. In addition, the rapid growth of niche markets for satellite and peripheral industries supplying information and communications technology products and specialized components and services have catapulted the knowledge based sector into the leading sector of the new economy of the 21st century.

The word global has taken on a new meaning since the emergence of the Internet more than three decades ago. The Internet has opened up countless opportunities for businesses and individuals worldwide. It has eliminated restrictions and borders regarding communication and interaction. It has archived an immense amount of information at our fingertips. Internetization has triggered an age of individual and collective empowerment that is unprecedented in our history

of civilization. It provides individuals, businesses and governments with a global influence and outreach. In short, Internetization has made time and geography irrelevant.

The ascendance of Internetization was propelled by the prominent role of human capital as a foundational characteristic of the new economy. The new global economy of the 21st century has given birth to a new and vibrant knowledge sector. More specifically, the knowledge based economy is fuelled by technology, human capital and research and development. This synergistic approach contributes to accelerating levels of productivity and economic performance. In short, the fuel of the new economy is technology and its currency is human capital. The product of the new economy is knowledge and its market is the virtual marketplace facilitated by the Internet.

FINANCIAL INTERNETIZATION

The most pervasive impact of Internetization on the economic landscape has been in the empowerment of electronic financing. Internetization is responsible for spearheading new economic, financial and commercial transactions. This takes the form of e-commerce, e-banking, electronic business transactions, instantaneous credit card purchases, debit cards, Internet bill payments, mobile phone financial transactions, electronic cash and the electronic transfer of capital. There is no denying that Internetization has facilitated the instantaneous convenience of digital financial transactions.

In most advanced industrialized countries, the use of cash and paper currency as a medium of exchange and a means for payment has declined dramatically. All of this as a direct result of the advent of Internetization in the form of electronic connectivity and capacity. There has also been a marked decline in the public demand for cash services along with a deliberate switching of financial transactions from paper cash to digital currency.

The economic impact of Internetization in terms of financial transactions is most discernible in Sweden. In this regard, Sweden has embraced and is acknowledged as a leader in the transformational process for switching from conventional currency into the digital medium. Sweden has become the role model for the effective application of Internetization in regard to conducting the modern era of financial transactions.

Swedish banks have been particularly enthusiastic about this transformation. They have eliminated ATM cash dispensing machines and promoted the use of digital currency. More specifically, Sweden's largest banks such as, SEB, Swedbank and Nordea Bank, have stopped manual cash-handling services in a large number of their local branches. This action is a consequence of their assessment that Swedes rely on credit cards, the Internet and mobile phones to make a significant portion of all their payments.

The Swedish Bankers Association has noted that "over the past few decades, the use of paper-based payments such as giro forms, cheques and cash payments have rapidly been replaced by electronic payments of various types. As an example, the use of different kinds of cards has increased from 100 million transactions in the middle of the 1990s to 1,956 million transactions in 2011. During the same period, the use of cheques has in practice ceased. While the share of electronic giro payments, mainly online, has increased, the share of paper-based giro transactions has decreased. The share of Swedes older than 15 years, who pay their bills through an Internet bank, has increased from 9 percent in 1999 to 79 percent in 2012. In the younger age groups (aged up to 34 years), up to 96 percent pay their bills through the Internet. During the same period, the use of paper based payments, such as giro forms, diminished from almost 79 percent in 1999 to 12 percent in 2012." (Swedish Bankers Association, 2013, p. 13). In consequence, the end of cash is a natural next step in an evolutionary process that has already led to the extinction of chequebooks.

It is worth noting that the transformational impact of Internetization on the scope and substance of financial transactions has exposed several vulnerabilities and fault lines on the contemporary digital landscape. The element of financial risk takes the form of identity theft, digital financial fraud, unauthorized electronic currency transfers, misappropriation of payments in the course of electronic consumer to business transactions and electronic credit card theft.

CYBER SECURITY

The rapid pace of technological innovation that has been the hallmark of the Internetization process has exposed the digital super highway to distinctive vulnerabilities. These take the form of hacking, malware infection, identity theft, electronic espionage, cyber terrorism and financial misappropriation.

It is becoming increasingly clear that the contemporary digital safeguards, firewalls and electronic locks do not offer a high level of personal privacy and cyber protection. Indeed, cybersecurity has become one of the foremost threats and negative side effects of Internetization. In particular, lapses in cybersecurity have exposed the inherent systemic risk of Internetization in the conduct e-commerce, e-banking, e-entertainment and e-communication.

On the contemporary landscape, advances in technological innovations are moving faster than the adoption of security protocols to police, control and protect digital connectivity. It is becoming increasingly prevalent on the contemporary digital network that security vulnerability in electronic devices has become systemic. This vulnerability may take the form of a successful cyber-attack that results in an invasion of privacy, access to personal emails, the remote high jacking of personal e-banking functions and the resetting of one's passwords. Ultimately all of this results in stealing a person's electronic identity.

The frequency of cyberespionage between countries has increased recently as a result of the availability of spy software and cyberespionage products. FinFisher, one of the best-known purveyors of spyware and cyberespionage training courses, has a clientele that includes countries and government agencies around the world. Modern cyberespionage products have the capacity to infect their targets' computers and phones, copy messages, record conversations and even activate webcams. The international media make headlines when they report on countries using cyberespionage to gain illicit electronic access and eavesdrop on their national neighbors, competitors, enemies and even members of their own political alliances.

The capacity of Internetization has been a great benefactor to the social media. Indeed, the impact of the social media on personal connectivity, business promotion, enhanced NGO's networks and government transparency have been massive. In some cases it has also created a big electronic headache. For example, the emergence of WikiLeaks, an international non-profit journalistic organization, whose mission is to expose secret information, news leaks and classified government documents has created considerable public embarrassment for some governments.

Electronic vulnerabilities and exposure are found in devices that do not offer protection from phishing emails, allow a backdoor access, can be remotely monitored and permit the tampering of an electronic smart security system. In consequence, there is an urgent need for a more effective partnership between government and manufacturers of electronic devices to enhance the security features of their devices in order to prevent the sophisticated hacking and the remote high jacking of those devices.

The next generation of cybersecurity will require an elevated level of personal identification, safer digital locks and the creation of impenetrable electronic firewalls. It has become abundantly clear that a PIN, username and password are simply insufficient and inadequate. The new generation

of cybersecurity will probably take the form of codified electronic locks, voice identification, finger print matching and eye retina protocols. All of this for the purpose of adopting fail safe cybersecurity systems that will protect individual identity, national security and corporate secrets in the digital age.

INTELLECTUAL PROPERTY

A cornerstone of the new economy has been the emergence of spectacular inventions, mass consumption innovations and digital connectivity. A consequence of this global electronic outreach has been the vulnerability of Internetization in regard to the protection of intellectual property. Indeed, the enforcement of intellectual property rights has become increasingly porous and elusive in a virtual and electronically borderless world.

The operational definition of intellectual property rights is the awarding of an economic monopoly to the inventor of an intellectual product or service. Intellectual property rights are foundational for the knowledge economy of the 21st century. In this regard, the conferring of intellectual property rights has legal stature and protection within most national jurisdictions. Examples of intellectual property rights are copyrights, patents, industrial designs and trademarks. The areas that are directly affected by intellectual property rights are music, literature, movies, different forms of artistic expression as well as mechanical, electronic and scientific inventions.

Intellectual property law became increasingly more prevalent in countries around the world in the latter half of the 20th century. Intellectual property rights have two foremost objectives. First, to reward inventors for their intellectual discoveries. Second, to provide an incentive for future inventors who will push the boundaries of intellectual achievement and in turn will propel economic growth and development.

The World Intellectual Property Organization (WIPO) was established in 1967 by treaty as an agency of the United Nations. It is worth noting that the WIPO Intellectual Property Handbook articulates the *raison d'être* of property laws in this manner:

“One is to give statutory expression to the moral and economic rights of creators in their creations and the rights of the public access to those creations. The second, is to promote, as a deliberate act of Government policy, creativity and the dissemination and application of its results and to encourage fair trading which would contribute to economic and social development.” (WIPO, 2015).

While the protection and enforcement of intellectual property rights prevails in most national jurisdictions, its enforceability across national borders is more problematic. There is no denying that Internetization has diluted the protection and enforcement of intellectual property rights. This is especially the case where the advancement of scientific knowledge has spawned new industries in the fields of biotechnology and nanotechnology and the originators of these new technologies have sought intellectual property protection.

On the contemporary digital landscape, electronic search engines like Kazaa and Gnutella represent a challenge for copyright policy. The Recording Industry Association of America has been at the forefront of the battle against electronic piracy and the enforcement of copyright laws. Modern legislation such as the Digital Millennium Copyright Act in the USA is an example of national attempts to thwart the consequences of malicious software and to enforce digital rights. Despite the contemporary legal protection and enforcement of intellectual rights, in 2011, trade in counterfeit copyrighted and trademarked products was a \$600 billion industry on an international scale and accounted for up to 7% of global trade (Bitton, 2012).

REDISCOVERING SCHUMPETER

The ascendance of the new economy requires a rediscovery of Schumpeterian theories. Schumpeterian theories have the potential of linking microeconomic derivatives to the macroeconomic postulates for economic growth and development. Indeed, Schumpeter's intellectual and theoretical legacy on the pivotal role of entrepreneurship and innovation is a vibrant analysis and laudable framework for determining the causal factors that promote economic prosperity and contribute to the wealth of nations in the 21st century (Passaris, 2001).

Schumpeter emphasized the predominance of sectoral economic analysis and the paramount importance of the entrepreneur as a catalyst for innovation and as the engine that drives economic growth and development. In this microeconomic scenario, innovation in the Schumpeterian model consisted of new products, new processes, new qualities of products, new sources of supply and new forms of business and industry organization. Essentially, it is a "process of industrial mutation.... that incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one" (Schumpeter, 1942, p. 79). It is in this context that he gives birth to his most famous phrase- "creative destruction" by which he means the replacement of old products, old enterprises and old organizational forms by new ones. The process of Internetization and its consequential impact on the new economy is a stellar example of the modern relevance of Schumpeterian theories.

Economic growth can only be sustained by finding new and better ways to utilize our limited and finite resources. In this respect, technological progress has always been an ingrained feature of national economies. Schumpeter's explanatory model for economic growth is focused primarily on the role of technological innovation. He proposed a model that postulated growth through the interaction of bursts of technological development

and competition between firms. Schumpeter saw capitalism as moving in long waves; every 50 years or so, technological revolutions would cause "gales of creative destruction" in which old industries would be swept away and replaced by new ones. Each wave of technology would fuel an upsurge in investment and create an impressive amount of job opportunities in new industries (Schumpeter, 1935). It is worth noting that the duration of the innovation cycle appears to be contracting over time from a 50 to 60 year duration to a shorter 30 to 40 year period. What has changed in recent times is the more rapid pace of technological innovation.

The role of the entrepreneur in the progression of the technological cycles was paramount. Schumpeter explains that "the function of entrepreneurs is to reform or revolutionize the pattern of production by exploiting an invention or, more generally an untried technological possibility for producing a new commodity or producing an old one in a new way, by opening up a new source of supply of materials or a new outlet for products, by reorganizing an industry and so on." (Schumpeter, 1942, p. 132).

Internetization is a vivid example of what Schumpeter describes as the process of creative destruction. In this context, Internetization has replaced old technologies with new and improved technologies. This is the process by which wealth and economic growth are achieved. It is also the process by which entrepreneurship creates its most important economic impact in the form of new investment, job creation and economic prosperity. In short, Internetization is the 21st century wave of Schumpeter's innovation cycles and provides contemporary confirmation that the technology life cycle is contracting over time.

The extrapolation of Schumpeter's microeconomic theories has the potential to form the theoretical construct for linking microeconomics with macroeconomics in the context of the new global economy of the 21st century. In this context, innovation and technological progress are an inherently microeconomic phenomenon, which are in turn a

consequence of optimum resource allocation and the profit oriented pursuits of economic activity. However, special mention should be made of the fact that they also result in the Schumpeterian waves of innovation and technological progress that have long term macroeconomic impact and consequences (Passaris, 2003).

In its microeconomic constructs, Schumpeter's concept of creative destruction embraces a multitude of features. These include innovation and obsolescence, the rise and fall of products and processes, entrepreneurial vision, risk and uncertainty, short term market advantage and abnormal profits. All of these microeconomic antecedents resonate with the process of Internetization and the creation of avant garde innovations. They also lead to positive long term macroeconomic consequences in the form of economic growth and development.

CONCLUSION

The advent of the new global economy of the 21st century has been empowered by momentous advances in technological innovation and the unprecedented outreach through digital capacity. In consequence, a new word, Internetization, is a more appropriate portrayal of the contemporary economic system with its virtual connectivity.

Internetization is the catalyst for transformative change on the modern economic landscape. It has precipitated unprecedented structural changes and redefined economic linkages on a global scale. Indeed, Internetization is playing a central role in the new global economy of the 21st century.

The economic profile of the new global economy is driven by technology, fueled by innovation and based on new ideas, new perspectives and new business strategies. Internetization is a process that is empowered by the information and communications technology revolution in a borderless world with a tremendous capacity for virtual connectivity.

FUTURE RESEARCH DIRECTIONS

The economic landscape of the 21st century is changing rapidly. Transformational change is the signature mark of the dynamic internetization process. Indeed, the impact of Internetization is not static; it is evolving and pervasive. Technological innovations are being introduced at record speed. The foundational structural changes that Internetization has precipitated have also triggered several intellectual fault lines that require focused research efforts in the near future.

Foremost among future research endeavors is the causal relationship between Internetization and the contemporary face of structural unemployment. Workers are being replaced as a result of technological innovations. Furthermore, they are having difficulty re-entering the workforce and transitioning to new employment opportunities. During the Industrial Revolution workers who were replaced by machines found work in the factories that made the machines. In the contemporary phase, chronic structural unemployment appears to have become a negative side effect of the Internetization process. The reason for the stubborn resistance of worker re-deployment during the Information Age is that the new jobs have raised the bar with respect to educational requirements, technical expertise and modern workplace competencies. This effectively renders the technologically unemployed ineligible for workplace re-integration.

Future research should also be directed towards ascertaining the scope of the evolving and pervasive nature of Internetization. The impact of technological advances and the consequences of electronic connectivity are both diverse and diffused. Indeed, the interactive nature of governance, economy and society in the context of a virtually interconnected world is a worthwhile research undertaking. This research endeavor will require an interdisciplinary and multidisciplinary approach. For example, the impact of Internetization has not been limited to the economic landscape, but has

also affected the political and governance process, the social values and communications etiquette of the new Information Age.

Another area for future research is in the domain of economic development. The hypothesis that requires analytical examination is the extent to which developing countries have benefited from Internetization. This research endeavor should explore whether Internetization is the great economic equalizer that has created a level playing field for economic development for both developed and developing countries. Alternatively, this research project will expose the extent to which developing countries have been adversely affected as a result of the lack of digital infrastructure and the cost of electronic connectivity. In consequence, this research endeavor will answer the question if Internetization has widened the gap between developed and developing countries or bridged the divide between developing and developed countries in regard to economic growth and individual prosperity.

KEY TERMS AND DEFINITIONS

Economic Globalization: The global integration of economies through trade and investment flows as well as the internationalization of the production of goods and services.

Financial Internetization: Internetization is responsible for spearheading new economic, financial and commercial transactions such as e-banking, e-commerce, instantaneous credit card purchases, debit cards, Internet bill payments, mobile phone financial transactions, digital cash and the electronic transfer of capital.

Globalization: A traditional concept that embraces international outreach and global linkages.

Internetization: A new word and concept that describes the empowerment of electronic connectivity on the new global economy.

IT Revolution: The information technology revolution has served as a catalyst for electronic connectivity, altered the production function, enhanced productivity growth, facilitated the collection of data, spearheaded the transmission of ideas and extended the reach of economic and social interactions.

Joseph A. Schumpeter: A 20th century economist who postulated the importance of entrepreneurship and innovation as the foundations for wealth creation.

New Global Economy: Describes the 21st century economy that is composed of a trilogy of interactive features that include globalization,

trade liberalization and the information technology and communication revolution.

Trade Liberalization: Also known as free trade encourages trade across national borders of goods and services, the legal transfer of intellectual property and the unregulated flow of financial capital.

An Efficient and Effective Index Structure for Query Evaluation in Search Engines

W

Yangjun Chen

University of Winnipeg, Canada

INTRODUCTION

Indexing the Web for fast keyword search is among the most challenging applications for scalable data management. In the past several decades, different indexing methods have been developed to speed up text search, such as inverted files, signature files and signature trees for indexing texts (Anh and Moffat, 2005; Chen et al., 2004; Chen et al. 2006; Faloutsos, 1985; Faloutsos et al., 1988); and suffix trees and tries (Knuth, 1975) for string matching. Especially, different variants of inverted files have been used by the Web search engines to find pages satisfying a query (Arasu, 2001; Lemple et al., 2003).

A text database can be roughly viewed as a collection of documents and each document is stored as a list of words. Over the documents, there are two kinds of Boolean queries, that is, queries that can be constructed from query terms by conjunction ($\wedge$) or disjunction ($\vee$). A document D is an answer to a conjunctive query $w_1 \wedge w_2 \wedge \dots \wedge w_k$ if it contains every w_i for $1 \leq i \leq k$ while D is an answer to a disjunctive query $w_1 \vee w_2 \vee \dots \vee w_l$ if it contains any w_i for $1 \leq i \leq l$. Conjunction and disjunction can be nested to arbitrary depth, but can always be transformed to a conjunctive normal form:

$$(w_{11} \dots \vee w_{1l_1} \dots) \wedge (w_{k1} \dots \vee w_{kl_k} \dots)$$

In this chapter, we discuss a new method to evaluate both conjunctive and disjunctive queries by decomposing an inverted list into a collection of disjoint sub-lists. The decomposition is based

on the construction of a trie structure T over documents and then associating each document word with an interval sequence generated by labeling T by using a kind of tree encoding.

With this method, we can improve the efficiency of traditional methods by an order of magnitude or more.

BACKGROUND

In order to efficiently evaluate such queries, indexes need to be established. It is well known that English texts typically contain many different variants of basic words, by using variant word endings such as ‘ing’, ‘ed’, ‘ses’, and ‘ation’. All the variants of a word should be regarded as a match and therefore it is efficient for an index only include these basic words, or say, stems. Different algorithms have been developed to extract stems from documents. Among them, the algorithm proposed by Lovins (1968) is widely used.

By the signature file, a word is hashed to a bit string (called a signature) and all the words’ signatures of a document are superimposed (bit-wise OR operation) into a document signature. When a query arrives, its signature will be created using the same hash function and the document signatures are scanned and many nonqualifying documents are discarded. The rest are either checked (so that the ‘false drops’ are removed) or they are returned to the user as they are. The main disadvantage of this method is the false drop (Kitagawa et al., 1997), which needs extra time to check. The signature file is greatly improved by the so-called signature tree (Chen et al. 2006),

by which a set of signatures is organized into a binary tree structure and a sequential search of signatures is replaced with a search of binary trees. However, signature-based methods can be used only for evaluating conjunctive queries. For disjunctive queries, they are not efficient.

As pointed out by many researchers (Anh et al., 2005; Ao et al., 2011; Zobel et al., 2006), the inverted file is a more competitive indexing method than signature-based approaches. It is extensively used by different web search engines due to its efficiency and simplicity. Structurally, it contains two parts: a search structure or vocabulary, containing all the distinct words to be indexed, and a set of inverted lists with each constructed for a distinct word w , storing the identifiers of all those documents containing w . Queries are evaluated by fetching the inverted lists for the query terms, and then intersecting them for conjunctive queries, or merging them (by a set union operation) for disjunctive queries. According to (Zobel et al., 1998), the inverted file is superior to the signature file in almost every respect, including functionality, query time, and space overhead.

Since it was first proposed in mid-1960s, the inverted file has been adopted in information retrieval, database systems, distributed systems (Büttcher et al., 2005; Camel et al., 2001), and different search engines. Also, much effort has been spent on the improvement of its performance by using integer coding (Golomb, 1966), bitmap compression (Apaydin et al., 2006; Bjørklund et al., 2009), caching (Saraiva et al., 2001), and parallelism (Ao et al., 2011). For a static environment, the bitmap compression is most efficient. However, it is obviously not suitable for a dynamical environment like the Web. So, different set intersection algorithms have been proposed to directly manipulate sorted arrays (Barbay et al., 2009), with caching (Barbay et al., 2009; Saraiva et al., 2001), parallelism (Ao et al., 2011), interpolation (Demaine et al., 2004), and even hardware characteristics (Tsirogiannis et al., 2009) being utilized to enhance performance. The method discussed in (Ding et al., 2011) is an in-

memory algorithm for set intersection, by which an inverted list is partitioned into a collection of sublists. Then, generate a hash image for each of them, by which a number in an inverted list is mapped to a single bit in an image. In this way, a set intersection is done by a series of hash value intersections.

INDEX STRUCTURES

In this section, we mainly discuss our index structure, by which each word with high frequency will be assigned an interval sequence. We will then associate intervals, instead of words, with inverted sub-lists. To clarify this mechanism, we will first discuss interval sequences for words in Subsection 1. Then, in Subsection 2, how to associate inverted lists with intervals will be addressed.

1. Interval Sequences Assigned to Words

Let $D = \{D_1, \dots, D_n\}$ be a set of documents. Let $W_i = \{w_{i1}, \dots, w_{in_i}\} (i = 1, \dots, n)$ be all of the words appearing in D_i , to be indexed. Denote $W = \bigcup_{i=1}^n W_i$, called the vocabulary. We define the word appearance frequency by the following formula:

$$f(w) = \frac{\text{num. of documents containing } w}{\text{num. of documents}}, (w \in W).$$

We then define a frequency threshold ζ . For any word w with $f(w) < \zeta$, we will associate it with an inverted list in a normal way, denoted as $\delta(w)$, exactly as in the method of inverted files. However, for all those with $f(w) \geq \zeta$, we will create a new index. For this, we will represent each D_i as a sequence containing all those words w with $f(w) \geq \zeta$, decreasingly sorted by $f(w)$. That is, in such a sequence, a word w precedes another w' if w is more frequent than w' in all documents.

Table 1. Documents and word sequences

DocID	Words	Sorted Word Sequence
1	<i>c, a, f, m, p</i>	<i>c, f, a, m, p</i>
2	<i>c, f, b, a</i>	<i>c, f, a, b</i>
3	<i>b, a, c, d</i>	<i>c, a, d, b</i>
4	<i>f, d, p, m</i>	<i>f, d, m, p</i>

In addition, for any subset of words that have the same appearance frequency a global ordering is defined so that in each sorted word sequence this global ordering is followed. In addition, we maintain a hash table H that maps each word w to its inverted list $\delta(w)$ or to its new index.

Example 1: In Table 1, we show a set of four documents, their words w with $f(w) \geq \zeta = 0.4$, and the corresponding sorted word sequences, where we use a character to represent a word for simplicity.

Notice that the global order on $\{f, a, c\}$ (with $f(w) = 0.75$) is set to be $c \rightarrow f \rightarrow a$ while the global order on $\{m, b, p, d\}$ (with $f(w) = 0.5$) is $d \rightarrow b \rightarrow m \rightarrow p$.

In practice, however, we can adjust ζ to include more words in the new index; and in the extreme case, all words can be included.

For each document $D_i (i = 1, \dots, n)$, we will use s_i to represent its sorted word sequence. Over all such sequences $S = \{s_1, \dots, s_n\}$, we will construct a digit tree, called a trie, as follows.

Assume that $W = \{w_1, \dots, w_m\}$. If $|S| = 0$, the trie is, of course, empty. For $|S| = 1$, $trie(S)$ is a single node. If $|S| > 1$, S is split into m (possibly empty) subsets $S_1, S_2, \dots, S_m$ so that a string is in S_j if its first word is w_j ($1 \leq j \leq m$). The tries $trie(S_1), trie(S_2), \dots, trie(S_n)$ are constructed in the same way except that at the k th step, the splitting of sets is based on the k th words in the sequences. They are then connected from their respective roots to a single node to create $trie(S)$. In Figure 1, we show a trie T constructed over the sorted word sequences in Table 1.

In the trie, v_0 is a virtual root, labeled with an empty word ε while any other node is labeled with a *real* word. Therefore, all the words on a path from the root to a leaf spell a sorted word sequence for a certain document. For instance, the path from v_0 to v_{13} corresponds to the sequence: *c, f, a, m, p*. Then, to check whether two words w_1 and w_2 are in the same document, we need only to check whether there exist two nodes v_1 and v_2 such that v_1 is labeled with w_1 , v_2 with w_2 , and v_1 and v_2 are on the same path. This shows that the reachability needs to be checked for this task, by which we ask whether a node v can reach another node u through a path. If it is the case, we denote it as $v \Rightarrow u$; otherwise, we denote it as $v \not\Rightarrow u$.

The reachability problem on tries can be solved very efficiently by using a kind of tree encoding, which labels each node v in a trie with an interval $I_v = [\alpha_v, \beta_v]$, where β_v denotes the rank of v in a post-order traversal of the trie. Here the ranks are assumed to begin with 1, and all the children of a node are assumed to be ordered and fixed during the traversal. Furthermore, α_v denotes the lowest rank for any node u in $T[v]$ (the subtree rooted at v , including v). Thus, for any node u in $T[v]$, we have $I_u \subseteq I_v$ since the post-order traversal enters a node before all of its children, and leaves after having visited all of its children. In Figure 1, we also show such a tree encoding on the trie, assuming that the children are ordered from left to right. It is easy to see that by interval containment we can check whether two nodes are on a same path. For example, $v_3 \Rightarrow v_{10}$, since $I_{v_3} = [1, 5]$, $I_{v_{10}} = [3, 3]$, and $[3, 3] \subset [1, 6]$; but $v_2 \not\Rightarrow v_9$, since $I_{v_2} = [10, 13]$, $I_{v_9} = [1, 2]$, and $[1, 2] \not\subset [10, 13]$.

Let $I = [\alpha, \beta]$ be an interval. We will refer to α and β as $I[1]$ and $I[2]$, respectively.

Lemma 1: For any two intervals I and I' generated for two nodes in a trie, one of four relations holds: $I \subset I'$, $I' \subset I$, $I[2] < I'[1]$, or $I'[2] < I[1]$.

Proof: The lemma can be directly derived from the definition of intervals.

Figure 1. A trie

However, more than one node may be labeled with the same word, such as nodes v_9 , and v_8 in Figure 1. Both are labeled with word m . Therefore, a word may be associated with more than one node (or say, more than one node's interval). Thus, to know whether two words are in the same document, multiple checking may be needed. For example, to check whether p and d are in the same document, we need to check v_{13} and v_{12} each against both v_7 and v_5 , by using the node's intervals.

In order to minimize such checks, we associate each word w with a word sequence of the form: $L_w = I_w^1, I_w^2, \dots, I_w^k$, where k is the number of all those nodes labeled with w and each $I_w^i = [I_w^i[1], I_w^i[2]]$ ($1 \leq i \leq k$) is an interval associated with a certain node labeled with w . In addition, we can sort L_w by the interval's first value such that for $1 \leq i < j \leq k$ we have $I_w^i[1] < I_w^j[1]$, which will greatly reduce the time for the reachability checking. We illustrate this in Figure 2, in which each word in Table 1 is associated with an interval sequence.

From this figure, we can see that for any two intervals I and I' in L_w we must have $I \not\subset I'$, and $I' \not\subset I$ since in any trie no two nodes on a path are labeled with the same word.

Finally, we point out that constructing a trie as above can be used as a general method for document classification. To see this, let's have a look at an example shown in Figure 3, which is part of an animal classification.

c :	$[1, 9]$
f :	$[1, 5]$ $[10, 13]$
a :	$[1, 4]$ $[6, 8]$
d :	$[6, 7]$ $[10, 12]$
b :	$[3, 3]$ $[6, 6]$
m :	$[1, 2]$ $[10, 11]$
p :	$[1, 1]$ $[10, 10]$

However, it is also a trie established using our method by checking the first several words in the corresponding document word sequences, where *animal* has the highest frequency while *mammalia*, *birds*, *fish*, and *amphibians* are less frequent.

2. Assignment of DocIDs to Intervals

Another important component of our index is to assign document identifiers to intervals. An interval I can be considered as a representative of

Figure 2. Sorted interval sequences

$c:$ [1, 9]
 $f:$ [1, 5][10, 13]
 $a:$ [1, 4][6, 8]
 $d:$ [6, 7][10, 12]
 $b:$ [3, 3][6, 6]
 $m:$ [1, 2][10, 11]
 $p:$ [1, 1][10, 10]

some words, i.e., all those words appearing on a *prefix* in the trie, which is a path P from the root to a certain node that is labeled with I . Then, the document identifiers assigned to I should be those containing all the words on P . For example, the words appearing on the prefix: $v_1 \rightarrow v_3 \rightarrow v_6$ in the trie shown in Figure 1 are words c, f , and a , represented by the interval [1, 4] associated with v_6 . So, the document identifiers assigned to [1, 4] should be {1, 2}, indicating that both documents D_1 and D_2 contain those three words. See the trie shown in Figure 4 for illustration, in which each node v is assigned a set of document identifiers that is also considered to be the set assigned to the interval associated with v .

Let v be the ending node of a prefix P , labeled with I . We will use $\delta(I)$, interchangeably $\delta(v)$, to

represent the set of document identifiers containing the words appearing on P . Thus, we have $\delta(v_6) = \delta([1, 4]) = \{1, 2\}$.

Lemma 2: Let u and v be two nodes in a trie T . If u and v are not on the same path in T , then $\delta(u)$ and $\delta(v)$ are disjoint, i.e., $\delta(u) \cap \delta(v) = \Phi$.

Proof: It is easy to prove.

Proposition 1: Assume that $v_1, v_2, \dots, v_j$ be all the nodes labeled with the same word w in T . Then, $\delta(w)$, the inverted list of w (i.e., the list of all the documents identifiers containing w) is equal to $\delta(v_1) \uplus \delta(v_2) \uplus \dots \uplus \delta(v_j)$, where $\uplus$ represents *disjoint union* over disjoint sets that have no elements in common.

Proof: Obviously, $\delta(w)$ is equal to $\delta(v_1) \cup \delta(v_2) \cup \dots \cup \delta(v_j)$. Since $v_1, v_2, \dots, v_j$ are labeled with the same word, they definitely appear on different paths as no nodes on a path are labeled with the same word. According to Lemma 2, $\delta(v_1) \cup \delta(v_2) \cup \dots \cup \delta(v_j)$ is equal to $\delta(v_1) \uplus \delta(v_2) \uplus \dots \uplus \delta(v_j)$.

As an example, see the nodes v_2 and v_3 in Fig. 5. Both are labeled with word f . So the inverted list of f is $\delta(v_2) \uplus \delta(v_3) = \{4\} \uplus \{1, 2\} = \{1, 2, 4\}$.

QUERY EVALUATION

Based on the new index structure, we design our algorithms. First, in Subsection 1, we introduce

Figure 3. Illustration for document classification

Figure 4. Illustration for assignment of document identifiers

the concept of word topological order, which is important to our query evaluation approach. Then, we present two algorithms to evaluate conjunctive and disjunctive queries in Subsections 2 and 3, respectively.

1. Word Topological Sequence

As shown below, using such interval sequences, the checking of whether two words are in the same document can be done in a very efficient way.

Definition 1: (Word topological order) Let $S = \{s_1, s_2, \dots, s_n\}$ be a set of n sorted word sequences. A word topological order over S is a sequence $\vartheta = w_1, w_2, \dots, w_m$, which contains all the words appearing in S such that for any two words w and w' if w appears before w' in some s_j ($1 \leq j \leq n$) then w appears before w' in ϑ , denoted as $w < w'$.

In Figure 2, the words are also listed (from top to bottom) in a word topological order with respect to the sorted word sequences given in Table 1. To find a word topological order over $S = \{s_1, s_2, \dots, s_n\}$ with $W = \{w_1, \dots, w_m\}$, we will transform the corresponding trie T to an acyclic directed graph

(DAG) G by splitting the node set of T (except for the virtual root) into m groups such that all the nodes in a group are labeled with the same word, and then collapsing each group g to a single node u . There is an edge in G from u (standing for a group g) to u' (for another group g') if T contains (x, y) with $x \in g$ and $y \in g'$. For example, the trie shown in Figure 1 will be transformed to a DAG shown in Figure 5(a).

Using a hash function H on the words in W , the transformation can be done in $O(|W|)$ time, by which all those nodes labeled with the same word w will be mapped to a single node identified by $H(w)$.

Let $G(V, E)$ be such a DAG. It is well known that only $O(|V| + |E|)$ time is required to find a *topological order* of G , which is a linear ordering of all its nodes such that if $u \rightarrow v \in E$, then u appears before v in the ordering. Replacing each node in the ordering with the corresponding word, we will obtain a word topological sequence, as illustrated in Figure 5(b).

2. Evaluation of Conjunctive Queries

We first consider a query containing only two words $w \wedge w'$ with $w < w'$. It is easy to see that

Figure 5. A transformed DAG

any interval in L_w cannot be contained in any interval in $L_{w'}$. Thus, to check whether w and w' are in the same document, we need only to check whether there exist $I \in L_w$ and $I' \in L_{w'}$ such that $I \supset I'$. Therefore, such a query can be evaluated by running a process, denoted as $conj(L_w, L_{w'})$, to find all those intervals in $L_{w'}$ with each being contained in some interval in L_w , stored in a new sequence L .

- Let $L_w = I_1^1, I_2^2, \dots, I_k^k$. Let $L_{w'} = I_1^{k'}, I_2^{k'}, \dots, I_{k'}^{k'}$. $L \leftarrow \emptyset$.
- Step through L_w and $L_{w'}$ from left to right. Let I_w^p and $I_{w'}^q$ be the intervals currently encountered. We will do one of the following checking:

- If $I_w^p \supset I_{w'}^q$, append $I_{w'}^q$ to then end of L . Move to $I_{w'}^{q+1}$ if $q < k'$ (then, in a next step, we will check I_w^p against $I_{w'}^{q+1}$).
- If $I_w^p[1] > I_{w'}^q[2]$, move to $I_{w'}^{q+1}$ if $q < k'$. If $q = k'$, stop.
- If $I_w^p[2] < I_{w'}^q[1]$, move to I_w^{p+1} if $p < k$ (then, in a next step, we will check I_w^{p+1} against $I_{w'}^q$). If $p = k$, stop.

Assume that $L = I_1, I_2, \dots, I_l$ ($l \leq k'$). Then, for each $1 \leq l_j \leq l$, there exists an interval $I \in L_w$ such that $I_j \subset I$, and we can return $\delta(I_1) \uplus \dots \uplus \delta(I_l)$ as the result. In Figure 6, we illustrate the working process on L_d and L_m shown in Figure 2.

Figure 6. Illustration of two-word checking

Figure 7. A merging process

Since in this process, each interval in both L_w and $L_{w'}$ is accessed only once, the time complication of this process is bounded by $O(|L_w| + |L_{w'}|)$.

The above approach can be easily extended to evaluate general queries of form $Q = w_1 \wedge w_2 \wedge \dots \wedge w_l$ with $w_1 < w_2 < \dots < w_l$ and $l \geq 1$ based on the transitivity of intervals:

$$I \supseteq I' \supseteq I'' \rightarrow I \supseteq I''.$$

What we need to do is to repeatedly apply *conj()* to the corresponding interval sequences associated with the query words one by one. Algorithm 1 is a formal description of this process.

It is easy to see that the time complexity of the algorithm is bounded by $O\left(\sum_{w \in Q} |L_w|\right)$, but can be further improved by using the binary, or galloping search, as well as the interpolation probing.

Example 2: Continued with Example 1. Let $Q = f \wedge m \wedge p$. Then, the execution of *containment**(Q)

Algorithm 1. Con-evaluation(Q)

```

begin
1.      let  $|Q| = l$ ; assume that
 $Q[1] < Q[2] < \dots < Q[l]$ ;
2.       $L := Q[1]$ ;
3.      for ( $j = 2$  to  $l$ ) do
4.      {  $L := \text{conj}(L, L_{Q[j]})$ ; }
5.      let  $L = I_1, \dots, I_k$ ;
6.      return  $\delta(I_1) \uplus \dots \uplus \delta(I_k)$ .
end
    
```

will find two containment sequences: $I_1 = [1, 5], [1, 2], [1, 1]$ and $I_2 = [10, 13], [10, 11], [10, 10]$. The results is then $R = \delta([1, 1]) \uplus \delta([10, 10]) = \{1\} \uplus \{4\} = \{1, 4\}$.

3. Evaluation of Disjunctive Queries

Similarly, we first consider a query containing only two words $w \vee w'$ with $w < w'$. For this, we define another process, denoted as *disj*($L_w, L_{w'}$), to merge L_w into $L_{w'}$, by which all those intervals I from L_w will be inserted into $L_{w'}$ if there is no interval in $L_{w'}$ is contained by I .

The operation can be efficiently conducted as follows.

Again, we will step through L_w and $L_{w'}$ from left to right. Let I_w^p and $I_{w'}^q$ be the intervals currently encountered. We will do the following checks:

1. If $I_w^p \supset I_{w'}^q$, move to $I_{w'}^{q+1}$ if $q < k'$. If $q = k'$, stop.
2. If $I_w^p[2] < I_{w'}^q[1]$, insert I_w^p into $L_{w'}$ just before $I_{w'}^q$. If $p < k$, move to I_w^{p+1} ; otherwise ($p = k$), stop.
3. If $I_{w'}^q[2] < I_w^p[1]$, move to I_w^{p+1} if $q < k'$. If $q = k'$, append $I_w^p, \dots, I_w^k$ to the end of $L_{w'}$ and then stop.

Example 3: Continued with Example 1. Let $Q = d \vee m$. We have $d < m$. By using the above procedure to merge $L_m = [1, 2][10, 11]$ into $L_d = [6, 7][10, 12]$, we will get a new sequence: $[1, 2][6, 7][10, 11]$. So, the result is

$\delta([1, 2]) \uplus \delta([6, 7]) \uplus \delta([10, 12]) = \{1\} \uplus \{3\} \uplus \{4\} = \{1, 3, 4\}$. In the first step, we compare $I_d^1 = [6, 7]$ and $I_m^1 = [1, 2]$. Since $I_d^1[1] = 6 > I_m^1[2] = 2$, I_m^1 will be inserted into L_d just before I_d^1 . Then, in the second step, we will compare I_d^1 and I_m^2 . Since $I_d^1[2] = 7 < I_m^2[1] = 10$, we will move to I_d^2 . Next, in the third step, we compare I_d^2 and I_m^2 , and find $I_d^2 \supset I_m^2$. Since I_m^2 is the last interval in L_m , we terminate the merging process and return the result.

Figure 7 shows the entire merging process.

By using the operation $disj(L_w, L_{w'})$, the algorithm to evaluate disjunctive queries of the form $Q = w_1 \vee w_2 \vee \dots \vee w_l$ with $w_1 < w_2 < \dots < w_l$ and $l \geq 1$ can also be efficiently implemented.

In Algorithm 2, we use $disj()$ to merge $L_{Q[i]}$ for $i = l - 1, \dots, 1$ into $L_{Q[1]}$ one by one. The running time is obviously bounded by $O(l \cdot r)$, where r is the largest number of intervals in all $L_{Q[i]}$'s which are not contained in each other. Again, the time requirement can be improved by using the binary search, the galloping search, and the interpolation probing.

CONCLUSION

In this chapter, a new index structure is discussed. It associates each word w with a sequence of intervals, which partition the inverted list $\delta(w)$ into a set of disjoint subsets. In this way, both the intersection (for conjunctive queries) and union (for disjunctive queries) of inverted lists can be done by checking the containment of intervals. This is much more efficient than the traditional inverted file method. Also, how to maintain such an index is described in great detail. Although the index is of a more complicated structure, the cost of maintaining it in the cases of addition and deletion of documents is (theoretically) comparable to the inverted file. Extensive experiments have

Algorithm 2. Dis-evaluation(Q)

```

begin
1.      let  $|Q| = l$ ; assume that
 $Q[1] < Q[2] < \dots < Q[l]$ ;
2.       $L := L_{Q[1]}$ ;
3.      for ( $i = l - 1$  downto 1)
do {
4.      {  $L := disj(L_{Q[i]}, L)$  };
5.      let  $L = I_1, \dots, I_k$ ;
6.      return  $\delta(I_1) \uplus \dots \uplus \delta(I_k)$ ;
end

```

been conducted, which show that our method outperforms the inverted file and the signature tree by an order of magnitude or more.

FUTURE WORK

As the future work, two issues need to be addressed: the binary search of interval sequences, and the use of *SIMD* (single instruction/multiple data) (Inoue et al., 2015) instructions. By the former, we will not scan an interval sequence linearly, but by the binary search. Especially, by using the *lowest common ancestors* (LCAs) of intervals (in a trie) in a binary search, the running time can be dramatically improved (Chen and Shen, 2015). By the latter, we will study how to arrange multiple processors to do the containment checking over multiple intervals simultaneously. That is, how to use SIMD instructions to do parallel checks of containments. In this way, the running time can also be significantly reduced.

KEY TERMS AND DEFINITIONS

Interval: A pair of integers $[a, b]$ where b denotes the rank of v in a post-order traversal of a trie. Here the ranks are assumed to begin with 1, and all the children of a node are assumed to

be ordered and fixed during the traversal. In addition, a denotes the lowest rank for any node u in the subtree rooted at v . Its purpose is to check the reachability. Let $[a, b]$ and $[c, d]$ be the intervals associated with v and u , respectively. If $[c, d] \subset [a, b]$, then u is reachable from v through a path in the tree.

Inverted List: (Also referred to as postings file or inverted file) an index data structure associated with a key word w , storing a set of document identifiers, which contain w . Its purpose is to allow fast full text searches, at a cost of increased processing when a document is added to the database.

Search Engine: A software used by the Internet to search data (as text or a database) for specified information; also, a server on the World Wide Web that uses such software to locate key words in other sites.

Set Disjunction: (Also called set union, denoted as $A \cup B$, where A and B are two sets) the set of elements which are in A , in B , or in both A and B .

Set Intersection: (Denoted as $A \cap B$, where A and B are two sets) the set that contains all elements of A that also belong to B (or equivalently, all elements of B that also belong to A), but no other elements.

Signature File: A set of signatures (bit strings) with each created for a document by superimposing (bitwise OR) all the word signatures. To find all the documents that contain a set of key words, we will first generate a query signature by superimposing all the query word signatures and then search the signature file to find its matching ones.

Trie: (Also called digital tree and sometimes radix tree or prefix tree as they can be searched by prefixes) an ordered tree data structure that is used to store a dynamic set of strings like texts and documents.

Improving Usability of Website Design Using W3C Guidelines

G. Sreedhar

Rashtriya Sanskrit Vidyapeetha (Deemed University), India

INTRODUCTION

Over the last few years there has been a remarkable increase in use of the World Wide Web (WWW) for a wide and variety of purposes. There was also a fast growth in its applications. This led the Internet users to realize the importance and the benefits gained from a globally interconnected hypermedia system. On the other hand it causes a larger number of useless, meaningless and badly designed websites on the Internet world causing unwanted additional traffic; this is all because of an unorganized non-planned websites development processes. Due to the unceasing growth of web sites and applications, developers and evaluators have interesting challenges not only from the development but also from the quality assurance point of view.

BACKGROUND

As we know, the quality assurance was and is one of the challenging processes in software engineering as well as for the web engineering, as a new discipline. Although there exists many design guidelines, and metrics for the evaluation of web sites and applications, most of them lack a well-defined specification framework and even worse a strategy for consultation and reuse. Some initial efforts have been recently made to classify metrics for some entity type as for example metrics for software products. Particularly, in last few years a set of web site metrics were defined and specified based on the data collection point

of view. The quality model must be able to assess the quality of each and every aspect of the website and it should cover the process of all web engineering activities. A set of guidelines are evolved to build a qualitative model of a website. According to Drefus P (1998) a guideline consists of a design and evaluation principle to be observed to get and to guarantee a usable user interface [1]. Guidelines can be found in many different formats with contents varying both in quality and level of detail, ranging from ill-structured common sense statements to formalized rules ready for automatic guidelines checking. Certain rules are validated by experimental results provided by user tests, experiments in laboratory or other techniques. Guidelines can be classified (Figure 1) by type ranging from the most general to the most specific: principles, guidelines and recommendations.

Principles are general objectives guiding conceptual User Interface (UI) decisions. They reflect the knowledge around human perception, learning and behavior and are generally expressed in generic terms like “Use images and metaphors consistent with real world” so that they can be applied for a wide range of cases. *Guidelines* are based on principles specific to a particular design domain. For example, a web design rule can stipulate to “use a consistent look and a visual language inside the site”. Some guidelines have to be interpreted more and altered to reflect the needs of a particular organization or a design case. *Recommendations* determine conceptual decisions specific to a particular domain of application and should reflect the needs and the terminology of a given organization. They are unambiguous state-

Figure 1. Website Guidelines and Sources

ments so that no place for interpretation is left. Recommendations include ergonomic algorithms, user interface patterns and design rules. Design rules are functional and operational requirements specifying the design of a particular interface, e.g. “Every web page needs an informative title”. Beirekdar A et al (2002) developed a framework to define a Guideline Definition Language (GDL) to investigate quality evaluation procedure. The GDL expresses guideline information in a sufficiently rich manner so that evaluation engine can perform GDL-compliant guideline.

$$\begin{aligned}
 U(p) &= f_{kwaremi}(Web_page, UES_{i,j}) \\
 &= EXEC(EC_{i,j} \{INST_UES_{i,j}\}) \\
 &= \{"Respected" | "Violated" | "Partially Respected"\}
 \end{aligned}
 \tag{1}$$

Where $UES_{i,j}$ be the set of evaluation sets associated to the guideline i in the source j and that will be used for the evaluation of the evaluated web page. $EC_{i,j}$ be the set of evaluation conditions associated to $UES_{i,j}$. $INST_UES_{i,j}$ is the set of captured instances of $UES_{i,j}$ in the evaluated page. In practice, the $f(Web_page, UES_{i,j})$ executes each $EC_{i,j}$ condition and then it combines the results to have the overall result for the guideline

i. We say that a web page satisfies a guideline $G_{i,j}$, if the execution of all $EC_{i,j}$ on all the $INST_UES_{i,j}$ is true. Using the above evaluation parameters allows us to define a kind of quality model to balance the evaluation result. In the accessibility field, Bobby, Valet, and EvalIris define a set of accessible evaluation tools. All these tools are based on accessibility guidelines. It does this through automatic checks as well as manual checks. It also analyzes web pages for compatibility with various browsers (eq. 3.2). Accessibility tools use a binary model to evaluate the accessibility of web pages (eq. 3.2).

$$Accessibility\ errors = \sum_{i=1}^{guidelines} a_i x_i \tag{2}$$

where a_i is 0 when guideline is violated and 1 when guideline is not violated and x_i is a guideline. A set of guidelines are considered to establish the procedure for Correctness of the Website. The World Wide Web Consortium (W3C) is an open source organizations and it defines various web standards for designing a website. The W3C is led by web inventor Tim Berners-Lee and CEO. The standards defined by W3C are considered as guidelines and these guidelines help in assessing

the quality of website content in presenting the web content. The guidelines are as summarized as follows.

Guideline 1: *Provide a text equivalent for every non-text element.* This includes images, graphical representations of text, image map regions, animations, applets and programmatic objects, frames, scripts, spaces, audio and video files.

Guideline 2: *Do not rely on color scheme only.* The content of web page must match with foreground and background color. Also provide sufficient contrast to the content for visibility.

Guideline 3: *Use markup and style sheets instead of images to convey information.* Style sheets controls the layout and presentation of the web page and decreases the download time of the web page.

Guideline 4: *Clearly mention the text information of web page with natural language.* Specify the expansion of each abbreviation or acronym in the document.

Guideline 5: *Use tables properly in the web document.* For data tables, clearly specify row and column headers and number of rows and columns exactly.

Guideline 6: *Ensure that web pages featuring new technologies transform gracefully.* When dynamic contents are updated, ensure that content is changed. Ensure that pages are available and meaningful when scripts, applets or other programmatic objects are not supported by the browsers. If this is not possible, provide equivalent information as alternative in the web page.

Guideline 7: *Ensure user control of time sensitive content changes.* Until user agents provide the ability to stop the refresh, do not create periodically auto-refreshing pages.

Guideline 8: *Ensure direct accessibility of embedded user interfaces.* Make programmatic elements such as scripts and applets directly

accessible or compatible with assistive technologies.

Guideline 9: *Design for device-independence.*

Ensure that any element that has its own interface can be operated in a device-independent manner.

Guideline 10: *Provide context orientation information.* Title each frame to facilitate frame identification and navigation. Divide large blocks of information into more manageable groups wherever appropriate.

Guideline 11: *Provide clear navigation mechanisms.* Clearly identify the target of each link. Provide information about the general layout of a site such as site map or table of contents.

Guideline 12: *Ensure that documents are clear and simple.* Create a style of presentation that is consistent across pages.

METHODOLOGY

In optimizing the correctness of website content different qualitative measures need to be investigated. These measures derived from the Web page errors that are generated using the W3C Validation Service. This process uses the standard web tool W3C HTML Validator to validate and identify the number of different errors according syntax errors of HTML tags, properties of web page and standards mentioned by various organizations such as W3C. Most pages on the World Wide Web are written in computer languages (such as HTML) that allow

Web authors to structure text, add multimedia content, and specify what appearance or style, the result should have. As for every language, these have their own *grammar*, *vocabulary* and *syntax*, and every document written with these computer languages are supposed to follow these rules. Markup languages are defined in *technical specifications*, which generally include a *formal grammar*. The tool compares HTML document

to the defined syntax of HTML and reports any discrepancies. The outputs of the Markup Validator are a list of error messages and their interpretation. W3C HTML Validator helps to ensure that documents are free of potential problems that can result in unexpected output when users view the bad documents with different browsers. A screenshot of W3C HTML Validator is shown in figure 2.

The errors related to website content cause incorrect display of some components of Web pages. These errors include:

1. **Table Tag Errors (TTE):** All the sub tags in table tag should be properly used in the web page design. Errors in table tag cause for display problems of web page.
2. **Body Tag Errors (BTE):** Body Tag Errors cause the errors in displaying the contents of the web page.
3. **Image Tag Errors (ITE):** Image Tag Errors cause for errors in downloading the image in a website.
4. **Head Tag Errors (HTE):** Head Tag Errors cause for errors in displaying heading and title of the web page.
5. **Font Tag Errors (FoTE):** Font Tag Errors cause the errors in textual display of the web page.
6. **Script Tag Errors (STE):** Script Tag Errors cause the errors in programming at client side scripting.
7. **Style Tag Errors (StTE):** Style Tag Errors cause errors in dynamic display features of the web page.
8. **Form Tag Errors (FmTE):** Form Tag Errors cause errors in input and output display of the script programming in a web page.

●	http://test.impressa.com/products/berfestipub.htm
●	http://test.impressa.com/products/yfftemplates.htm
●	Document type does not allow element "div" here.

Priority	URL / Description
●	This image is corrupt. This can be caused by the following: • running out of disk space quota during image file upload • transferring the image using FTP text mode • saving the image with the wrong extension (e.g. saving as JPEG, but using a .gif)
●	http://test.impressa.com/usa/base/hoofound.png
●	This link is broken. The page could not be found on the target web server.
●	This link is broken. The target anchor does not exist or is commented out.
●	This page contains some spelling errors. Click the word to add it to the dictionary or ignore it.
●	http://test.impressa.com/privacy.htm
●	This link requires a username and password.
●	5 issues on 17 pages

9. **Link Tag Errors (LTE):** Link Tag Errors cause errors in linking various web components.

The web content errors are occurred due to non-standards of web site design. The developer must be attentive in using HTML tags so that appropriate tags should be used in web design process. All the tags and their attributes properly set and closed accordingly. This will reduce the problem of web page display and avoids the problem in downloading of the web page.

Website optimization is required in the following areas in order to improve the correctness of the website.

1. **Text Presentation:** Text Presentation is an important issue in display of the web content. These issues should be properly handled in presenting 100% correct text presentation. Several literature sources provide guidance about appearance of text on the web page. To format the text on web page the developer should consider following properties in text presentation.
 - Fonts must be chosen among the most readable ones.
 - Font size must be defined as relative size
 - Use fonts designed for computer screens rather than fonts designed for print
 - In a single page, the number of different fonts must be limited.
 - When using different fonts and font sizes, they should have some specific meaning (e.g. notes, links, and navigation location).
 - Avoid italicizing and underlining text.

These properties can be detected and measured by parsing both the text and CSS. The above properties are defined as attributes in various HTML tags. These tags include <HEAD>, <BODY> and tags. The errors in attributes of tag

errors cause incorrect or semi correct display of text on web page. The algorithm QAPM identifies the errors related to text presentation. Thus the Head Tag Errors (HTE), Font Tag Errors (FoTE) and Body Tag Errors (BTE) identify the problems in the text presentation of web page.

2. **Link Presentation:** The link presentation is important aspect in organization of web pages. The links in a website may be internal or external links. There are differences among the internal and external links. While internal links must all be valid and links pointing to external domains are out of control of the webmaster, but can be checked. Link topology is an often neglected aspect. Some sites are just trees of nodes, with links from a node pointing to children and to ancestors. Some others have a much more complex link topology, with many horizontal or traverse links. To format the links on the web page perform following functions.
 - Use moderate levels of breadth with minimal in the information architecture.
 - Minimize depth.
 - Avoid broken links.
 - Use corresponding text links.
 - Redundant links may cause confusion and avoid them.
 - Effective navigation requires small pages, few clicks between pages and strong scent.

Thus Link Tag Errors (LTE) and broken links identify the problems in link presentation.

3. **Page Layout:** The page layout is probably the principal characteristic perceived by the user. Layout must be clean, and the whole content should be well structured. A page layout is designed using tables, <div> tag or <frame> tag. Layout must adaptable to different devices. This implies that page must

avoid making reference to specific device settings, like screen resolution or fixed size page components. An automated analysis of CSS usage and coding can supply information about the layout and the adoption of an organization wide standard. The algorithm QAPM generates table tag errors (TTE), frame tag errors (FTE), style tag errors (StTE), font tag errors (FoTE), frame tag usage errors and document type declaration errors if any attribute of tag element deviate the properties of page formatting. The Page Formatting Measures assess the following features of website.

- Use browser-safe colors.
 - Use no more than 6 discriminable colors.
 - Use 256 (8-bit) color palettes.
 - Avoid using black backgrounds.
 - Use high contrast between background and text.
 - Keep line lengths to 40-60 characters
 - Keep text between 9 to 15 words per line.
 - Avoid using framesets.
 - Text should cover no more than 25-30% of the screen.
 - Greater text density facilitates page scanning.
4. **Graphics Presentation:** The graphic presentation is the important issue in presenting pictorial and multimedia components. *To format Graphics on the web page* perform following properties should be followed.
- Avoid using graphical text links.
 - Use corresponding text links instead of graphical links.
 - Avoid using animation unless it is appropriate.
 - Proper contrast between foreground image and background (color or image).

The image tag error (ITE), body tag errors (BTE) and image load errors related to image

identifies the errors in display of images and hence Graphic Element Measures to be evaluated. Graphics Element Measures developed for assessing the following features of web interfaces.

5. **Page Performance:** Correctness is a merely technical aspect, which can be easily checked. In many cases inconsistent behaviour with different browsers can be originated by lack of conformance to the published grammars (HTML, XHTML) and the default actions taken by the browsers themselves. Correctness is easily checked as an internal quality factor. The important aspects to consider in some environments are the professionalism and effectiveness of the web site that could be measured through how many different platforms are supported and it supports adaptivity and adaptability for a personalization Etnoteam et al (2000), M.Y. Ivory (2001). The form tag errors (FmTE), script tag errors (STE) and title tag with no keyword errors identify the need of page performance measure. The page performance measures developed to answer the following questions related to the website. To increase the performance of the web page following guidelines are considered.
- Minimize the use of video.
 - Avoid using sound files.
 - Effective navigation requires small pages.
 - Avoid using 'Click Here' for link text.

The contents of website must be presented in such a way that the user has to get 100% satisfaction in viewing all web pages of the website so that complete content of website visible and all pages are accessible. At this part of the research paper, it is tried to evolve 10-point scale. Thus 10-point scale is a metric towards defining quality of web content. In this connection it is interpreted the 10-point scale indicates such that '0' always represent poorer side and '10' always represent the best side of quality aspect. The 10-point scale metrics

for various qualitative measures are formulated using empirical evaluation. Here 10-point scale of web content depends on the value computed using measures and its level competence based on performance.

$$k = \left(\frac{n}{10} \right) * \text{No. of Pages with errors} \quad (3)$$

$$\text{Correctness} = (10 - k) \quad (4)$$

where n is number of Web Pages in a Website

Very Good if Correctness ≥ 9

Good if Correctness ≥ 8

Better than Average if Correctness ≥ 7

Average if Correctness ≥ 6

Below Average if Correctness ≥ 5

Poor if Correctness ≥ 4

Very Poor otherwise

(5)

Table 1. Quality Status of University Websites in India

S. No	University	No. of Pages With Errors (Per 100 Pages)	Correctness	Performance
1	English and Foreign Language University, Hyderabad	29	7.1	Better than Average
2	Moulana Azad National Urdu University, Hyderabad	93	0.7	Very Poor
3	University of Hyderabad, Hyderabad	96	0.4	Very Poor
4	Rajiv Gandhi Nagar University, Itanagar	14	8.6	Good
5	Assam University	38	6.2	Average
6	Tezpur University	45	5.5	Below Average
7	Central University of Bihar	87	1.3	Very Poor
8	Nalanda University	13	8.7	Good
9	Central University of Haryana	45	5.5	Below Average
10	Central University of Himachal Pradesh	8	9.2	Very Good
11	Central University of Jammu	12	8.8	Good
12	Central University of Kashmir	7	9.3	Very Good
13	Central University of Jharkhand	13	8.7	Good
14	Central University of Karnataka	19	8.1	Good
15	Central University of Kerala	87	1.3	Very Poor
16	Guru Ghasidas Viswavidyalaya, Bilaspur	17	8.3	Good
17	Dr. Harisingh Gour Viswavidyalaya, Sagar	54	4.6	Very Poor
18	Indira Gandhi National Tribal University	36	6.4	Average
19	Mahatma Gandhi Antharashtriya Viswavidyalaya	18	8.2	Good
20	Central Agricultural University, Manipur	22	7.8	Better than Average

EVALUATION

The study was conducted on 20 University websites using the methodology discussed in section 3 and the results are shown in Table 1.

CONCLUSION

The main theme of the chapter is to provide optimization techniques to improve the correctness of the website. It is observed that website must be informative and all contents of the website must be accommodated in page layout according to standard guidelines. An attempt is made to enhance the quality of website content and layout so that web designer shall follow the quality of content in designing a web site.

FUTURE RESEARCH DIRECTIONS

The chapter shows the way for the development of quality web designing in all aspects of websites. This is very much necessary to provide Quality of Service (QoS) to the online users. The chapter is well illustrated with a case study so that one can easily identify the defects in their own websites. The research work done in this chapter is the basis path for further extending the research in web engineering.

KEY TERMS AND DEFINITIONS

Correctness: A merely technical aspect, which can be easily checked. Correctness is easily checked as an internal quality factor. The important aspects to consider in some environments are the professionalism and effectiveness of the web site that could be measured through how many different platforms are supported and it supports adaptivity and adaptability for a personalization.

Graphics Presentation: The graphic presentation is the important issue in presenting pictorial and multimedia components.

Guidelines: Consists of a design and evaluation principle to be observed to get and to guarantee a usable user interface.

Link Presentation: The link presentation is important aspect in organization of web pages. The links in a website may be internal or external links.

Text Presentation: Text Presentation is an important issue in display of the web content. These issues should be properly handled in presenting 100% correct text presentation.

W3C HTML Validator: The outputs of the Mark up Validator are a list of error messages and their interpretation. W3C HTML Validator helps to ensure that documents are free of potential problems that can result in unexpected output when users view the bad documents with different browsers.

Website Content: The collection of web pages organized on a Web server. Web pages are of two types, static and dynamic.

Website Errors: Website errors related to website content cause incorrect display of some components of Web pages.

Internet Phenomenon

Lars Konzack

University of Copenhagen, Denmark

INTRODUCTION

Internet phenomenon is a new field of research. An internet phenomenon is an occurrence on the internet about somebody, a website, or a picture that for some reason captures the attention of numerous internet users and develops a craze that fast-spreads through the internet. The most common internet phenomenon is an internet meme, but also internet celebrities, political campaigns, or simply something out of the ordinary.

BACKGROUND

Before the internet there were the existence of folk tales and urban legends, folk songs and oral poetry as a way share content (Duggan, Haase, & Callow, 2016). Internet phenomena have often been compared to folklore and urban legends; however there is one significant difference in that folklore was passed on in an oral culture of illiterates. Internet on the other hand sharing are mostly done among 21st Century literates and often stored on servers for other people to see. In this sense sharing internet phenomena are closer to chain letters except the internet technology makes the process a lot easier and faster and may spread globally within minutes.

“Ideas are transmitted, often without critical assessment, across a broad array of minds and this uncoordinated flow of information is associated with “bad ideas” or “ruinous fads and foolish fashions.” (Jenkins, Ford, & Green, 2013, p. 307)

With 21st Century computer technology any idea or creation has the potential to spread like wildfire globally on the internet and if they do they become internet phenomena.

DOI: 10.4018/978-1-5225-2255-3.ch697

INTERNET MEMES

The most common internet phenomenon is an internet meme. The idea of memes takes it root in the memetics of Richard Dawkins but the concept of internet memes have evolved since then. Internet memes has become part of everyday life on the internet. Research has been done to understand this internet phenomenon as regards the development of internet memes, categorization of memes, and how they work.

An Internet meme is defined as a motif that is virally disseminated through the Internet. The motif often undergoes lots of variations (mash-ups) and may consist of sound, picture, movie clip, game and written text, or as is mostly the case, a combination by two or more modalities. Moreover the motif can be connected to only one of these modalities but need not be and in such case may enter different kinds of modalities.

It is difficult to pinpoint the first internet meme. One could argue that the emoticon introduced as the smiley in September 19th 1982 with all the variations of the theme is in fact the first internet meme (Rosenträger, 2008).

The term meme stems from Richard Dawkins controversial work *The Selfish Gene* referring partly to gene and partly to mimeme, which means to imitate. In his use of the term it is considered as any cultural idea or behavior such as fashion, language, religion, science and sports – cultural DNA reproducing itself (Dawkins, 1976). It is unclear whether Richard Dawkins comprehends the meme as an objective structure, or a metaphor for cultural practices. However, recent use of the term of internet meme has outgrown Richard Dawkins and has become a phenomenon in its own right (Stryker, 2011). According to Mole Empire the

ten most famous internet memes as of 2011 are as follows Keyboard Cat, Three Wolf Moon, Om Nom Nom, Auto Tune, The David After Dentist, Penaut Butter Jelly Time, Christian Bale Rant, Fail, O RLY, and Numa Numa (Smith, 2011). While this of course is by no means based on real academic research, it still gives a clue as to what these internet memes are.

A more systematic approach comes from Know Your Meme (<http://knowyourmeme.com/>), given that they try to accommodate a database of all known internet memes, and as of 2015 they have collected more than 13,000 meme entries of which at least 2,400 are confirmed, and they have categorized them as regards to confirmation status, what year it came to be, and where on the internet it originated. Wikipedia has descriptions of some of the most famous internet memes. An internet researcher may likewise find descriptions of internet memes on Oh Internet (<http://ohinternet.com>). On a far more chaotic scale it is possible to find information about internet memes on Encyclopedia Dramatica (<http://encyclopedia-dramatica.se>) although it requires skill to understand the in-jokes and to select the right bits of information and knowledge about internet memes. However, with the skill to comprehend Encyclopedia Dramatica, there is indeed information as regards to origins and explanations to a lot of these memes, information that may be difficult if not impossible to achieve by other means, and Encyclopedia Dramatica provides the right context and attitude for these memes, which the other catalogues do not.

Observation of how memes develop can be done, at websites such as YouTube, 4chan, 9gag, reddit, YTMND and Tumblr. While a lot of these memes originates from YouTube or 4chan the key to their success is the viral dissemination through e.g. E-mails, Facebook or Twitter. Memes can also be made by the use of so-called meme generators. These are internet services on which the user can upload images or use a wide range of ready-made images and put in a text-caption.

Since internet memes are a new phenomenon only few studies of have been made and they have all been experimental in their approach, some of which are presented here.

STUDYING MEMES

A study of Internet memes was conducted by Michele Knobel and Colin Lankshear (Knobel & Lankshear, 2007). They suggest an approach to memes based on three characteristics of memes that according to Richard Dawkins is the key to a successful meme: fidelity, fecundity, and longevity. Fidelity is how replicable the meme is. Fecundity is the dissemination speed. And longevity is the staying power of the meme. Furthermore the memes have been analyzed using three general axes: referential or ideational system, contextual or interpersonal system, and ideological or worldview system. During their research, they found that successful memes had three key components: humor, rich intertextuality (references to other works of art), and anomalous juxtaposition (mash-ups of deliberate provocative or off-guard instances of absurdity). Furthermore they made a categorization of internet memes primarily dividing into three groups: 1) social commentary purposes, 2) absurdist or humor purposes, and 3) otaku and manga fan purposes.

Another approach comes from Colin Stryker that conducted his own research of the meme life cycle that he lays out as seven stages (Stryker, 2011). The seven stages are as follows: birth, discovery, aggregation, word of mouth, blog pickup, mainstream exposure, commercialization, and death. It must be added that Colin Stryker says that not all memes goes through this exact life cycle. Some never become mainstream and other jump over certain stages, or follow a different path in order of sequence.

The birth of the meme is where and how it originated. A discovery of the meme could be that if someone posts the meme on a web-com-

munity like 4chan and is immediately picked up by the other users with mash-ups and comments. Aggregation begins when the meme jumps from the web-community that first discovered the meme to other web-communities like Reddit. Word of Mouth is actually more like dissemination through means of electronic written text and uploading images or movies, using blogs, tweets, status updates and instant messaging. It only reminds of actual word of mouth in the sense that it is distributed via informal means. Blog pickup happens when the specialized internet sites like 9gag, YTMND, Tumblr, and Know Your Meme receives and propagates the meme. It is at this stage the meme becomes a part of the general internet culture with self-referential jokes and clever mash-ups. Mainstream exposure of the meme occurs when old media like television, radio and newspapers distributes the story of the meme. It is at this stage the main stream population outside the internet culture learns about the internet meme, and it is paradoxically at that point where the inner circle of the internet culture may lose interest in the meme. Then there is only commercialization left (e.g. turning the meme into some sort of merchandise) before the meme is almost death, disappeared and forgotten.

In a study of YouTube memes conducted by Limor Shifman various meme features are recognized (Shifman, 2011). First of all Shifman discusses the difference between a viral video and a memetic video, in which a viral video is a video clip that spreads without significant change, while a memetic video is a popular video clip that 'lures extensive creative user engagement in the form of parody, pastiche, and other derivative work' (p. 190). The recognized Limor Shifman key features of YouTube memes are as follows: They relate to 'ordinary' people, and are often about flawed masculinity. They use humor, simplicity and repetitiveness, and portray whimsical content.

Patrick Davison argues that in order to understand internet memes, we will have to specify what exactly is being replicated (Davison, 2012).

According to Davison a meme can be separated into three components: manifestation, behavior, and ideal. The manifestation is the actualized as an observable, external phenomenon in time and space. The behavior is the action taken by users and producers of the meme. And the ideal of the meme is the idea conveyed as a conceptual purpose. The ideal determines the behavior which again resolves into the manifestation.

All of these approaches to internet memes demonstrate first of all that it is a new field that needs to be further studied but it also shows that these people take it very seriously and come up with ways to grasp and comprehend internet memes. They are trying to categorize them, understand how they function, how they develop over time, and how we should perceive them as cultural expression.

INTERNET CELEBRITIES

An internet celebrity is a celebrity known on the internet, and maybe even in old media as well, through at least one internet meme. In many cases this celebrity status has been notorious or ill-famed rather than the more positive kind of renown and fame. Due to the spreadability of internet memes, these meme celebrities have got lots of attention (Jenkins, Ford, & Green, 2013).

In November 2002, a Canadian high school student, Ghyslain Raza, made a video of himself playing with a golf ball retriever as if he was fighting like Darth Maul from Star Wars Episode 1: The Phantom Menace (Knobel & Lankshear, 2007). The video was uploaded to Kazaaby some of his classmates without his knowledge. The video became known as Star Wars Kid, went viral as a global hit, because people found it hilarious to see how a heavy-built kid was using all his energy to immerse himself into the role of a Sith Lord. The video was manipulated in different ways with sound and light effects, and lots of images were made based on the original video. Ghyslain Raza

W

had unknowingly become an Internet sensation. Ghyzlan became the laughing stock of millions and did not get anything else out of it (Stryker, 2011).

Numa Numa is the popular name of the music video *Dragostea din tei* by the Moldovan pop-group O-Zone, and it became notorious when overweight 19 year old Gary Brolsma in December 2004 lip synched to the video, waving his arms around. He later appeared in *Good Morning America*, and in 2006 he made his own website with merchandise and a remix of the original song (Stryker, 2011). Although Brolsma became laughed at he could at least cash in his fame.

David After Dentist is a video clip by his seven year old son David after his visit to the dentist, filmed by his father in May 2008. Seven months later he uploaded the video to YouTube (Prout, 2010). It became an instant sensation, and David was considered funny as well as cute. David along with his father appeared in *Today Show*, *Tyra Banks Show* and *The O'Reilly Factor*. The father detected a business opportunity, got a website, and made more video clips of his son, selling T-shirts and other merchandise. There has been controversy as to whether or not it was ethical for his father to exploit his own son like that (Linkins, 2009).

Another internet phenomenon was Boxxy. She made a couple of videos about herself to internet friends from a website called Gaia, and uploaded the videos to YouTube as BoxxyBabee in January 2008. This wasn't dramatic until 4chan came across the videos a year later and decided it was either the worst they had ever seen or the cutest girl on the internet. Memes were made in her honor as either cancer or as queen. She was portrayed as a girl version of Che Guevara and sold as T-shirts by meme merchandise internet shops. Little did she know what was going on until her mail account was hacked and all of her personal files was spread across the internet. Later she tried with mixed luck to cash in her sudden fame (Stryker, 2011).

Rebecca Black on the other hand tried to be famous by making a music video. On February 2011, the 13 year old girl uploaded the music video

to YouTube and it turned viral. And people hated it. The song *Friday* came to be the most hated song on the internet and viewed by millions. The ill-famed girl was ridiculed through countless of memes (Stryker, 2011). She did however make an appearance as Katy Perry's friend in Katy Perry's music video for *Last Friday Night (T.G.I.F.)*.

The face of Laina Morris became known as *Overly Attached Girlfriend* (Lagore, 2015). It was based on a video uploaded June 6th 2012 named *JB Fanvideo* for a Justin Bieber song competition. The starring eyes of Laina Morris and the song about an overly attached girlfriend made her face known to the internet. She has coped with the fame by posting other videos, and on March 11th 2013 she appeared on the show *Late Night with Jimmy Fallon*.

But not only people become famous. Products may become well-known as well. *Three wolf Moon* was a black T-shirt with three wolves howling at the Moon sold on Amazon. The T-shirt sold well but wasn't anything in particular, when suddenly a guy made a false review of the T-shirt stating that you would get all the girls you wanted if you wore it. The review was written in a humorous tone and others joined in, making their own reviews. After a while it spread across the internet with images superimposing the T-shirt to famous people and some music videos were made as well, and the T-shirt became a bestseller (Stryker, 2011).

For this reason or just for the fun of it many internet users have tried to create their own internet memes, hoping they will catch on. These are made on purpose and for the most part they fail. It is much more fun if the internet meme seems to come out of nowhere, like a coincidence or accident. These pushed memes are considered unfunny and are called forced memes. Within the depths of internet culture forced memes are frowned upon (Nissenbaum & Shifman, 2015).

Since internet phenomena have had such a tremendous impact, they have been used for propaganda purposes as well. Anonymous, the freedom fighters from 4chan, have used internet memes countless of times to spread their point of

view across the internet. On Project Chanology, their ongoing revolt against Scientology, they used the Guy Fawkes Mask (Stryker, 2011). It is correct that it originates from Guy Fawkes and the comic book and the later movie *V for Vendetta*. However, it was actually used at the time as a meme called Epic Fail Guy, which featured a dancing cartoon-like figure wearing the mask. The message to Scientology was that they were epic fail. They used other known memes like Rickrolling, and Longcat as well. As Anonymous progressed into support for WikiLeaks, Arab Spring, and the Occupy Movement it became a symbol of an internet youth rebellion. It became a sign of the times (Coleman, 2014).

Internet memes have been used in the American election for either candidate as far back as 2008, and have become a part of the campaign strategy in which each candidate produce forced memes to either a positive portrayal of their own candidate or a negative portrayal of the other candidate (Tay, 2015).

OTHER INTERNET PHENOMENONA

There are lots of internet phenomena and it is not possible to show all them here. This is just a few examples to show the range of diversity of internet phenomena.

Beany Babies have been said to be the first internet phenomenon. In the 1990s Beanie Babies attracted bidders on eBay more than any other item category. In May 1997, the average price for a Beany Baby was \$30, generating a total Beany Babies turnover of \$500.000 on eBay. By the end of the decade the sales plummeted to a more reasonable price around 50 cents apiece (Bissonnette, 2015).

Creepypasta are horror stories spread on the internet that are creepy. They are very close to urban legends except they are spread not through word-of-mouth but via internet as written or au-

diovisual communication that can be saved. The term creepypasta comes from a portmanteau of creepy and cospypasta – cospypasta meaning stories that are copied and pasted. The most common creepypasta is Slender Man which is a character of a tall man abducting children. It took the world by storm and made a lot of people scared or anxious. Slender Man was originally created by Erik Knudsen who in June 2014 apologized that it was taken too seriously (Delaney & Madigan, 2016).

Another internet phenomenon is Let's Play (or LP). LP was promulgated by the website Something Awful and is video footage of someone playing and commenting a videogame – often shared on YouTube or. The focus is not on the player but what happens in the game. It's a mixture of review, general commenting on the game and how it is played and advice on how to play the game. Most notably is PewDiePie, whose real name is Felix Arvid Ulf Kjellberg, with almost 50.000 subscribers (Berry, 2015).

Kony 2012 was a failed attempt at arresting Joseph Kony, an Ugandan war criminal, by the end of 2012. Kony 2012 was the title of a short documentary that was shared on the internet with over 100 million views. Although the video got a lot of attention and a resolution condemning the terror of Joseph Kony from American senators, and even President Obama offering a reward of \$5 million for his arrest, Joseph Kony has still not been captured (Mahoney & Tang, 2016).

In 2014, Ice Bucket Challenge arose among people to donate money to amyotrophic lateral sclerosis (ALS). They should take the challenge of having ice cold water poured over them and challenge three others to donate and be poured over by cold water. This chain letter approach meant that a lot of people came in contact with the Ice Bucket Challenge and eventually a lot of celebrities participated. The Ice Bucket Challenge was often shared as YouTube videos on the internet and raised \$114 million dollars (Hutchins & Tindall, 2016).

FUTURE RESEARCH DIRECTIONS

There is still lot to be done as far as future research in the field of internet meme, and we have yet to see their cultural, sociological and political impact. Internet phenomena are used, reproduced and part of a participating internet culture. One of the most interesting future research directions would be to see the development of political internet memes and the link between geek culture and popular culture in relations to internet phenomena. There is a lot of internet phenomena that cannot be analyzed by a single individual. Future research will demand digital humanities solutions to delve into the many aesthetic and cultural aspects of internet phenomena.

CONCLUSION

As we have seen internet phenomena can be analyzed as far as categorization, functionality, development, and as a socio-cultural phenomenon. Research has shown how internet memes are born; how they develop over time; and how they eventually die. It has shown how internet memes may be categorized into three major subgroups: 1) social commentary purposes, 2) absurdist or humor purposes, and 3) otaku and manga fan purposes. An internet meme consists of three components: 1) manifestation, 2) behavior, 3) and ideal. The spreadability of internet phenomena means that indeed internet celebrities have arisen, and we have seen some examples of these. Furthermore a range of different internet phenomena has spawned and disappeared again.

KEY TERMS AND DEFINITIONS

Internet Meme: A motif that is virally disseminated through the Internet. The motif often undergoes lots of variations (mash-ups) and may consist of sound, picture, movie clip, game and

written text, or as is mostly the case, a combination by two or more modalities. Moreover the motif can be connected to only one of these modalities but need not be and in such case may enter different kinds of modalities.

Internet Phenomenon: An occurrence on the internet about somebody: a website, or a picture that for some reason captures the attention of numerous internet users and develops a craze that fast-spreads through the internet.

Manga: Japanese comics style.

Otaku: A Japanese term for obsessive collector – often manga-related items. It is commonly used as the Japanese term for a geek or nerd.

Spreadability: The ability to disseminate information.

An Overview of Crowdsourcing

Eman Younis

Minia University, Egypt

INTRODUCTION

During the past decade, there were rapid developments in the Internet, computing technologies, wide-spread and use of location-aware technologies such as GPS and mobile phones.

These developments influenced how people communicate and share their opinions, views, knowledge, maps, and many others throughout software platforms. These technologies have participated in the creation of what is now called Web 2.0, which is a new era of web technologies enabling users to play an active role in adding contents to the web in a collaborative way, instead of just consuming the web contents.

People are now easily sharing social media posts, blog posts, product reviews, ideas, opinions, maps and others. Crowdsourcing is characterized as a phenomenon that appeared due to enabling web users to contribute to the web.

There are many online Crowdsourcing applications such as Amazon Mechanical Turk, Open Street Map, and Yahoo Answers amongst others. Thus, crowdsourcing is a collaborative process which involves four main components (requester, crowd, open call and platform). People might benefit financially or intellectually from participation in crowdsourcing. This chapter serves as a general overview of crowdsourcing research and envisages future research directions.

BACKGROUND

Due to the invasion of pervasive computing and Web 2.0 technologies (Brabham, 2013), users can not only consume information on the web

by search and navigation but also, contribute their own contents. Crowdsourcing is also called fan sourcing, crowd casting, mass collaboration, socio-technical systems (Geiger, D. et al. 2012), collective intelligence, smart mobs, peer production, citizen science and user generated content (Haythornthwaite, 2009).

Many applications have been created to make use of the online crowds such as Question Answering, Mapping, Software Engineering, Healthcare and many more. Examples of Crowdsourcing systems are yahoo answers, Open Street Map, Amazon Mechanical Turk, among others. Crowdsourcing can be classified according to (Howe, J. 2008) into co-creation, crowd creation, crowd voting, crowd wisdom, and crowdfunding.

There is always confusion between the terms crowdsourcing and outsourcing. Here we distinguish between these terms. Wikipedia has created a debate; some researchers do not consider it a crowdsourcing site. Because it is not satisfying their 8 criteria listed in (Estellés-Arolas et al. 2012). On the other hand (Haythornthwaite, 2009) considers Wikipedia a crowdsourcing platform, contributed by a collection of volunteer contributors.

This chapter presents a general overview of the crowdsourcing field. It is structured as follows; it begins with the analysis of definitions of the term from literature followed by a classification of crowdsourcing activities. Then, a comparison between crowdsourcing and outsourcing is presented. After that a discussion of crowd-user motivations is presented. It also presents the benefits and problems of crowdsourcing, its applications, online crowdsourcing systems, current and future research avenues.

CROWDSOURCING DEFINITIONS

Crowdsourcing is not a new phenomenon; it has been used in the past in many cases for collecting users' participations (Howe, J. 2008). But, until now there is no standard agreed upon definition of crowdsourcing. The term was first proposed by Jeff Howe's in a Wired Magazine article (Howe, J. 2008) and defined as:

the act of a company of institution taking a function once performed by employees and outsourcing it to an undefined and generally large network of people in the form of open call.

After that, there were several other attempts to define it in the literature such as (Ambati et al. 2012 Azzam, T. et al. 2013, Von Ess 2010, Bell, 2009, Doan et al. 2011, Lebraty et al. 2013, Brabham, 2013, Estellés-Arolas et al. 2012, Sharma et al. 2014 and many more). These definitions are different in their view regarding the targeted application of crowdsourcing. The definitions of Crowdsourcing are unified in terms of the general concepts and components, but, targeting different applications.

Figure1 depicts the crowdsourcing process, showing various components. The first component is the sourcer or the requester, which can be an organization or an individual. The requester wants to accomplish a specific goal or solve a problem. This goal can be to create, test, or rate a product or a service or it can even be to collect capital investment to initiate a project. The second component is an open call (this is the call for participants to contribute to achieving the requester's goal). The third component is the crowd (the anticipated contributors to the open call). The last component is the platform that facilitates the process of interaction between the requester and the crowd. Figure1 depicts the crowdsourcing process, showing various components. It shows that the crowdsourcing process is initiated by the requester, which may be a company, an institution or an individual, having some problem to solve. This requester sends an open call for participations to the crowd. The diversity and heterogeneity of the crowd capabilities are an advantage, which produces variations of the presented solutions. The crowd participates in the open call by providing solutions to the problem. The requester receives and evaluates the presented solutions.

Figure 1. The Crowdsourcing process

CLASSIFICATION OF CROWDSOURCING ACTIVITIES

Crowdsourcing activities can be classified into the following categories (Howe, J. 2008):

- **Crowd Wisdom:** There are some tasks which require human intelligence, such as text or image classification, tagging or annotation. The crowdsourcing system collects several human-annotated examples from the crowd to be used for computer learning. In such applications, the crowd wisdom has been used to help the computer solving a hard problem. As an example, Amazon Mechanical Turk (www.mturk.com) is offering paid work for the crowd to solve human Intelligence tasks (HITs) called micro-tasks. Another example is (<https://www.google.com/recaptcha>), where users are acting voluntarily to support Google performing intelligent tasks such as text and image recognition automatically. These kinds of tasks are essential for Machine Learning applications.
- **Crowd Creation:** In this type of crowdsourcing, the crowd is asked to contribute some kind of artifacts, designs, maps or even a question and its answer. For example (threadless.com), is a company offering its customers a share of profit for the best T-shirt design. Another example in mapping is (Open Street Map), which is an online free mapping platform, where anyone can share their own maps or use existing maps. It is mainly based on the volunteer contributions from the crowd. Moreover, Question Answering Services such as (<https://answers.yahoo.com/>) are depending on the crowd for creating questions and answers. Wikipedia is another example of crowd creation tasks, where the crowd collaborates to create an encyclopedia.
- **Crowdfunding:** It is a recent phenomenon depending on collecting financial funding

for establishing a project or financing an idea. The idea behind its success is finding the interested crowd in the suggested project or idea. An example is (sellaband.com) asking for donations from their crowd-fans to sponsor their music albums.

- **Crowd Opinion or Crowd Rating:** In these systems, the crowd worker is required to provide his/her feedback or opinion in an artifact, design or even rate a piece of software. This type of systems can be used to evaluate the outputs of the previous types of systems using the crowd opinions.
- **Crowd Solving:** This type of crowdsourcing usually involves a contest for the crowd to solve a specific problem. For example, (www.kaggle.com) is an online crowdsourcing system for scientific problem solving. It encourages participants by giving financial prizes for the best solutions. Another example in the scientific field is (www.researchgate.net), where any researcher can send his problem and receive answers from his/her peers.

Although Howe, J. 2008 first presented crowdsourcing as an outsourcing activity, there are potential differences between those two concepts. Despite being aiming to get a task or a job done by people outside the organization boundary, there are still differences between the two terms. The next section shows the differences between them.

CROWDSOURCING VERSUS OUTSOURCING

Although Jeff How's definition of Crowdsourcing presented earlier as an outsourcing activity, outsourcing is a different concept. Outsourcing is the process of hiring an external company to provide a product or a service. Here we want to clarify that outsourcing is different from crowdsourcing in many aspects. First, outsourcing is the process throughout which the company contract

with other external company to provide a product or a service, whereas in the crowdsourcing process the company sends an open call of participations to the crowd. Thus, the differences between both processes involve three points (Sharma and Padmanaban, 2014):

1. **Contract:** In the outsourcing process, there is a contract between the main company and the specified outsourcing company. Whereas, in the crowdsourcing process, there is no contract between the sourcer and the crowd.
2. **Cost:** The contract entitles the sourcer company to pay a pre-determined amount of money according to the contract. The crowdsourcing could involve volunteering work from the crowd or pay a nominal amount of money.
3. **Commitment:** The company involved in the outsourcing is committed to abiding by all the contract conditions by delivering product or service on time and specifications required. But, the crowd is free of any obligations to participate or give good quality outputs.

Figure 2 shows the difference between crowdsourcing and outsourcing.

USER MOTIVATIONS FOR CONTRIBUTION

It is important to know why people are engaged in crowdsourcing activities. Motivations are the stimulating factors that encourage people to do actions. Ryan et al. 2000 presented the crowd motivations to participate to Intrinsic and extrinsic motivations. The intrinsic motivations are defined as those leading to enjoyment or any type of satisfaction for the participant. Extrinsic motivations are those triggered by a separate outcome such as a reward. Pilz et al. 2013 discussed different incentives of participants in crowdsourcing. They further divided the user incentives more fine-grained classes out of the essential intrinsic and extrinsic proposed by (Ryan et al. 2000). They further divided the intrinsic motivations into enjoyment-based containing (skill variety, task identity, task autonomy, time killing and feedback) and community- based including (community

Figure 2. Crowdsourcing versus outsourcing

identification and social contact). Whereas, the extrinsic motivations were further sub-divided into immediate payoff (payment), delayed pay-off (Signaling and human capital advancement) and social motivation (action significance by external values, action significance by external obligations and norms and Indirect feedback from the job). Regarding the company, there are also gains out of crowdsourcing which will be discussed in the next section.

BENEFITS OF CROWDSOURCING

There are a lot of benefits for the company to use crowdsourcing. These benefits as presented by (Stol and Fitzgerald, 2014) are as follows:

1. **Cost Reduction:** Using crowdsourcing for doing a task is financially effective, as the cost of hiring online crowd is much less than hiring internal employees for performing the same task. The crowd may even do the work voluntarily. In addition to the cost reduction, using the crowd gives indications of the actual needs of the customers.
2. **Faster Time-to-Market:** Using the crowd makes the production process more effective, as the task can be done in less time.
3. **Higher Quality:** Crowdsourcing allows harnessing the diversity of experiences and knowledge of the crowd. This leads to higher quality solutions.
4. **Higher Creativity and Innovation:** By receiving many contributions from the crowd, which are having a wide variety of experiences, mentalities and geographically distributed different cultures. This gives more opportunities to have more creative and innovative ideas.

PROBLEMS OF CROWDSOURCING

1. It is difficult to estimate the project budget, as the participants will vary in size.

2. It is challenging to produce a precise specification of the problem, to present it to the crowd.
3. The crowd structure is missing.
4. Legal considerations, regarding who has the intellectual property of the contents.
5. Balancing the incentive motivations of the crowd (Extrinsic and intrinsic).
6. Problems regarding using crowdsourcing for software development are discussed in (Stol et al. 2014) as task decomposition, coordination and communication, planning and scheduling, quality assurance, Knowledge, and intellectual property.

CONCEPTUAL MODELS OF CROWDSOURCING

Conceptual models are abstractions and simplifications of the real world systems. Conceptual models are different from software design and implementation. An example of a conceptual model is the E-R (entity - relationship) diagram in database design, which is the logical design of the database, and then it is used for creating the physical database. Pedersen, J. et al. 2013, presented a conceptual model for crowdsourcing from the information systems perspectives. This conceptual model presents the basic input processing output components of Crowdsourcing. It is important to classify the research relating it to the information systems research community. The basic components of this proposed model are presented in Figure 3.

1. **Problem:** The specifications of the current situation and the tasks required to obtain a solution. The problem can be co-creation, crowd creation, crowd wisdom or crowd funding (Howe, J. 2008). Research related to the problem is concentrating on goals and tasks (Wiggins et al. 2012), and mechanisms for the evaluation of ideas (Blohm et al. 2011)

Figure 3. Crowdsourcing Conceptual Model (Pedersen, J. et al. 2013)

and user selection of a problem to contribute (Peddibhotla, 2013).

2. **Process:** Is the actual plan to solve the problem. The problem can be simple, one stage solution, such as product design or voting. It also can be a complex problem that requires a multiple-stage solution such as software development. Research targeting the processes includes collaborative e-science design (Farooq et al. 2009) and modeling information sharing process (Grant et al. 2010).
3. **Technology:** Acts as the enabling component to the crowdsourcing process. The technology involves not only the software platform, which facilitates the interaction between the sourcer and the crowd but also, tools supporting the online community creation. ICT technology and crowdsourcing (Davis, 2011), (Tilson et al. 2010).
4. **Governance:** These are the rules and regulations that organize the whole process of crowdsourcing. It also includes the rules for consistency preserving and quality assurance. Research involves quality control (Lasecki et al. 2012), (Lease, 2011) and crowdsourcing activity coordination (Zhang et al. 2011).

5. **People:** People participating in the crowdsourcing process are divided into three classes. The first is the crowd, all the possible participants. Second, the individual is the person who participates in the crowdsourcing process. Third, the problem owner can be an individual, an organization or a company having a problem aiming to solve. Research tackled the types of participants (Cullen et al. 2011), user motivations (Pilz et al. 2013)
6. **Solution:** The output of the crowdsourcing process. It can be a product, a design, a piece of software, or a rating of any of the previous artifacts. Research address the sourcer feedback (Moon et al. 2008), (Bao et al. 2011) and solution trustworthiness (Zhai et al. 2012).

Additionally, Malone et al. (2010) suggested a gene-based model for studying crowdsourcing systems. His model is composed of the following questions:

1. **What? (Goal or Mission)**
In this question the requester decides which tasks need to be performed, either create a new product or service or decide between different available options.

2. **Who? (Staff)**
The answer to the first question helps to decide the audience. Who will be the targeted participants and also determine the suitable software platform for the required task. If the task can be done by organization employees, the tasks can be assigned to them. Otherwise, it will be better to use crowdsourcing, where there are more varieties of tools and experiences.
3. **How? (Process)**
This refers to how the task will be accomplished, the useful tools and the results evaluation criteria. Considering the way in which the problem will be divided into smaller tasks. Moreover, deciding on the integration of the results to form a solution to the problem.
4. **Why? (Incentives or Motivations)**
This involves incentives of the crowd to participate. There should be a balance between intrinsic motivations, which are related to the participants and extrinsic, which is something external such as prize or money.
3. **Geospatial Mapping:** The term volunteered geographic information (VGI) suggested by Goodchild, 2007 has become very popular, with the spread of geographic mapping platforms, which allows the public to contribute their own maps and GPS traces. Examples are Open Street Map and Google My Map.
4. **Scientific Research:** There are many platforms that facilitate the research and collaboration in scientific problem solving such as (innocetive.com) and (researchgate.net).
5. **Decision Support:** Organizations learning from the crowd (Schlagwein et al, 2014) and (Chiu et al 2014) presented a framework for using the crowd to enhance the decision support for organizations.
6. **New Product Design:** Poetz et al, 2012 compared between using the crowd and employees for designing tasks. He concluded that crowdsourcing is a promising approach to product design.
7. **Medical Applications:** King et al. 2013 held a comparison between conventional methods and crowdsourcing methods for Skin self-examination. He argued that using crowdsourcing has a potential in the cancer detection task. Brabham et al. 2014 presented a framework for using crowdsourcing in public health applications. Meyer et al. 2016 proposed the use of crowdsourcing for medical diagnosis.
8. **Machine Learning and Prediction:** Tong et al. 2014 presented an approach to use crowdsourcing for race results prediction. Demartini, et al. 2013 proposed an approach to use the crowd for identifying similar items in the Linked Data. Scharl et al. 2012 presented an approach for the use of crowdsourcing in the acquisition of multi-lingual language data sets. Zhang et al. 2012 demonstrated using the crowd for web page clipping, which is useful for pattern mining applications. Sprugnoli, et al,

CROWDSOURCING APPLICATIONS

Crowdsourcing has been applied in many applications

1. **Software Development, Testing, and Engineering:** Using crowdsourcing for software development is a challenging process as it is a complex process, comprising of multiple stages and activities. It has been extensively discussed in (Stol et al. 2014), (LaToza et al, 2016) and Sharma et al, 2014).
2. **Question Answering:** Questions answering Systems (QAS) are software systems accepting user questions in natural language and presenting exact answer. They are becoming more popular with crowdsourcing user questions and answers. Yahoo Answers and Google Answers are examples of community QAS.

- 2013 presented the use of crowdsourcing for speech translation.
9. **Sales and Design:** Crowdsourcing has been used in product design to boost sales. This has been the idea used by (Threadless.com) by giving its customers the chance to send their own T-shirt designs. Then, different designs were evaluated and the designs with most sales are entitled to share profit with the company (Howe, J. 2008).
 10. **Crowdsourcing in Media:** Nylund, et al. 2014 demonstrated the role of crowdsourcing in the media industry. The authors claimed that the spread of social media sites among the crowds has created the potential for growing the citizen journalism. In other words, it has become easier for the public to capture the events as soon as it happens and spread it out throughout social media sites.
 11. **Marketing:** Doing marketing research and collecting crowd ideas and opinions about products or services during or after development is essential for business. (Whitla, 2009)
 12. **Optimization:** (Yi et al. 2011) demonstrated the use of crowdsourcing for the traveling salesman optimization problem.
 13. **Disaster Management:** (Gao et al, 2012), suggested the use of social media as a crowdsourcing platform for disaster relief.

Figure 4. Crowdsourcing platforms

PLATFORM	TASKS	MOTIVATIONS
TopCoder. (http://www.topcoder.com)	• Crowd Creation and Innovation. • Users participate in solving, designing or creating software.	• Extrinsic Motivations (Users are paid for the completed tasks)
Amazon Mechanical Turk (www.mturk.com)	• Micro-tasks (Crowd creation) • Acquire user input to evaluate a design or measure a particular criterion that requires human intelligence. • Purpose: Crowd rating, Crowd tagging and Crowd creation.	• Extrinsic motivations used to encourage participants. • People are paid a nominal amount of money for every task completed.
Crowdflower (http://www.crowdflower.com/)	• An online platform for collecting data from people around the world. • Purpose: Micro-task (Crowd creation and rating tasks)	• Extrinsic motivations used by paying contributors.
DesignCrowd (http://www.designcrowd.co.uk/)	• An online service to harness user innovations in designing a logo, web page, T-shirt, Brochure or business card. • Crowd creation.	• Extrinsic motivated by payment per design.
InnoCentive (http://www.innocentive.com/)	• Online based challenges for users to solve.	• Extrinsic motivations by giving awards for best solutions.
Istockphoto (http://www.istockphoto.com/)	• Open challenge for photographers to send their own photos and videos. • Crowd creation.	• Extrinsic motivations by giving credits that can be used by users to download their favorites.
(mobileworks) www.mobileworks.com	• An online crowdsourcing platform for business data collection. • Crowd creation task.	• Extrinsic Motivations. Participants are paid for their online work.
Kaggle (www.kaggle.com)	• An online crowdsourcing platform for data science competitions. • Crowd creation.	• Extrinsic Motivations. The best solvers are paid for their work.
http://www.crowdsourcing.com	• An online crowdsourcing platform for data science competitions. • Crowd creation.	• Extrinsic motivations. Users are given money for their participations.
www.utest.com	• An online crowdsourcing platform for testing software. • Crowd rating.	• Extrinsic motivations.

CROWDSOURCING PLATFORMS ON THE WEB

There are a plethora of Crowdsourcing platforms available online. Table 1 shows different available crowdsourcing platforms with their associated tasks and user motivations. Crowdsourcing platforms are different from crowdsourcing systems also in the user motivations. All the crowdsourcing platforms have extrinsic motivations.

FUTURE RESEARCH DIRECTIONS

Crowdsourcing has been an active research area for ten years. Although a lot of research has been done in many areas such as business, behavioral science, and computer science, there is still more to be done. First regarding the *problem*, it is critical to present the calls for participations in a way suitable for the intended audience and finding the suitable audience for the problem. This needs to be per application customization. A possible research question can be what are the criteria that determine the suitability of the individual to participate in certain crowdsourcing application? Second, regarding the *process*, there is a need for a unified set of processes for each crowdsourcing application context. Third, *technology*, it is important to integrate web2.0 technologies such as wikis blogs and social media with new technologies for crowdsourcing such as sensors, which are now widely available in mobile phones. Fourth, *governance*, it is crucial to control the whole process throughout presenting evaluation methods for every element in the systems starting with the problem specification to the final output. Fifth, *people*, studying user motivations for contributions is an important aspect, it needs to be studied per application, as it helps in future systems design. Finally, *the output* is the final solution to the problem presented by the crowd. It is essential to quantify the quality of the proposed solutions, in order to, select the best one. Thus, a concise set of procedures for measuring the quality of the

solution are needed. Moreover, it is essential for the organization or the individual to ensure that the intended goals of crowdsourcing have been achieved. Another issue is how to detect and avoid cheating from the crowd and create trust among the crowd members and between the requester and the crowd. Regarding applications, it is of interest to investigate the use of crowdsourcing with the semantic web and showing the differences imposed by these technologies.

W

CONCLUSION

Crowdsourcing is a promising research area which has proven success in many applications. It has been an active research area over the past ten years and it is anticipated to grow in the future, due to its endless applications. Using the crowd thinking and experience could give the organization new and innovative ideas that could never be possible using only the internal organization resources. Thus, crowdsourcing presents great opportunities for value creation in areas such as business, Information systems development, machine learning data collection and many more.

KEY TERMS AND DEFINITIONS

Crowd: A group of people from geographically distributed locations, different professions, and different cultures.

Crowdsourcing Platform: A more generic online crowdsourcing system, designed for multi-purpose. It can be used for multiple tasks such as product design, rating or voting and data collection tasks. An example is Amazon Mechanical Turk.

Open Source: The act of developing software for free usage and distributions. It is not only for free usage, but also, for free modifications.

Outsourcing: The process used by companies to get a product or a service done externally by other people or companies.

User Incentives: Motivational factors that are used to encourage the crowd to participate in a crowdsourcing activity.

Web 2.0: A set of tools such as social media, wikis and blogs, which made it possible for people to create and share their own contents on the web. The further advancements of using the Semantics and linkage are called Web 3.0.

W

Revisiting Web 2.0

Michael Dinger

University of South Carolina Upstate, USA

Varun Grover

Clemson University, USA

INTRODUCTION

Though well over a decade old now, the term Web 2.0 was intended to capture a wave of technologies that indicate advancement beyond the original Web 1.0, which was dominated by tightly controlled, relatively static websites. As such, Web 2.0 represents a set of technologies that enable high levels of interactivity and participation via the internet. It is an umbrella term that describes a variety of dynamic and community-based web initiatives that place value on the power of distributed knowledge, leverage data, and provide users with rich multimedia experiences (O'Reilly, 2005). Web 2.0 technologies have given rise to the dominance of social media which over 65% of U.S. adults use (Perrin, 2015). Furthermore, Web 2.0 technologies are now inherent throughout the modern web, but are also increasingly embedded throughout the milieu of digital technology, including mobile platforms and cloud services. Web 2.0 technologies and their associated changes in internet usage enable new forms of data collection and data analytics, including social network analysis and social media analytics (Chen, Chiang, & Storey, 2012). As a result, it is useful to revisit the core technological components of the Web 2.0 wave and to consider how these elements have become embedded throughout modern business applications and how the technologies can add value for consumers and businesses. Cutting edge firms can leverage such technologies to create integrated solutions that improve their relationships with customers and enrich customer experiences.

Many businesses create additional value for users and customers by leveraging the voluntary participation of users through interactive technologies. For example, Amazon offers extensive product support through an interactive set of tools supporting customer interactions. Customers can leave product reviews for their past purchases. However, Amazon also provides a question and answer system, wherein prospective customers can ask questions about a product and previous buyers are able to respond, with the answers posted on the product listing page. The application of interactive technologies enables Amazon to create value without extensive organizational labor, but instead harnesses the power of their existing customer base to create valuable content.

Businesses continue to capitalize on this set of technologies in a variety of ways. Many companies leverage interactive technologies by capturing customer data and leveraging it to generate instantaneous, custom-tailored customer experiences (Bodoff & Ho, 2015). For example, Netflix aggregates and analyzes subscriber movie preferences in order to provide accurate movie recommendations. Similarly, Pandora, the internet music service, creates customized radio stations for individuals based on their expressed preferences. However, Pandora also mines user data to customize targeted advertising to each user (Singer, 2014). Furthermore, businesses can leverage Web 2.0 technologies in order to dynamically cooperate with customers and partners in efforts to generate new design innovations (Roberts & Dinger, 2016; Roberts & Grover, 2012; Wong, Peko, Sundaram,

& Piramuthu, 2015). Both online and traditional businesses must understand how to navigate and capitalize on the changing internet terrain to stay competitive in the Web 2.0 era.

BACKGROUND

Web 2.0 thinking emphasizes the distributed and interactive nature of information technologies. Therefore, the core concept of a web page is altered to allow for quick and efficient interaction from users. This mindset is represented in the way that users can create, remove or edit informational content on wikis, comment on blogs or content aggregation sites like Reddit, or drive the content of media-sharing sites like YouTube. The distributed nature of Web 2.0 technologies allows many users to create and participate while needing little technical knowledge.

Characteristics of Web 2.0

Web 2.0 technologies can be identified by a number of common characteristics. These technologies generally capitalize on the ability of website users to actively participate, including the capacity to dynamically contribute content and network with other users. Web 2.0 initiatives are dynamic in nature, enabling constant change and updates. Also, Web 2.0 technologies regularly include social networking elements which enable users to form connections with one another. Finally, these endeavors are noted for their reliance on the distributed contributions of many participants.

Distributed Contributions

The primary driver behind Web 2.0 technologies are the ability of firms to harness the value of distributed contributions from many users. Wikis inherently rely on the contributions and efforts of many users. The intent of wikis is to represent a culmination of the knowledge of all participating users. Media platform sites like YouTube, Instagram, Tumblr and Flickr entirely consist of user

contributions. Facebook has opened up its software platform so that users can create and contribute original applications (developers.facebook.com). Similarly, Apple has enabled a wide range of developers to create new and innovative applications for the iOS ecosystem (developer.apple.com) as has Google with the Android ecosystem (developer.android.com). The ability to harness the distributed contributions of many participants plays a significant role in a firm's ability to generate value from these initiatives.

Dynamic Nature

The dynamic nature of Web 2.0 technologies is driven by their ability to be quickly changed. A core design element of wikis is the ability to add, remove or change content quickly. On social networking sites, users are able to add, modify and remove content ease. Content platforms like Twitter, Instagram, and Vine thrive on the speed of content creation and sharing. By focusing on a small piece of content, users can rapidly create and share content, such as a 140 character post, an image, or a 6 second video, respectively. The speed of movement can be a double-edge sword, as it enables companies to quickly interact with customers to resolve problems, or for upset users to share stories of bad customer service that go viral. For example, a United Airlines customer created a YouTube video to share how the airline broke his guitar and would not reimburse any of the damages, and a \$1,200 guitar ended up costing the airline far more in bad publicity (Sawhney, 2009). In another case, a Comcast customer service representative would not simply comply with a customer's request to cancel their service. The customer recorded the call and posted it online on SoundCloud, where it went viral with bad publicity for Comcast (Diamond, 2015).

Rich Media

Rich media is a common characteristic of Web 2.0 technologies. Many online sites and app platforms are compiled solely of user-generated

content, including YouTube, Instagram, Tumblr and Flickr, but rich media can enhance any user experience. For years, many news sites, such as CNN.com and ESPN.com, have embedded video in conjunction with print stories. However, the technology has become ubiquitous, with local TV channels and newspapers commonly posting video in conjunction with news stories.

Social Networking Elements

Social networking leverages people-to-people interactions. For example, blog users can form connections to other bloggers. Analysis suggests that users of media sharing websites, specifically YouTube, can engage in social networking activity through the manner in which they manipulate access to their contributed media (Lange, 2007). Finally, social networking platforms can be embedded in a variety of different websites.

ARCHETYPES OF WEB 2.0

The Web 2.0 trend popularized three general archetypes of technology: blogs, wikis, and social networking sites (SNS). Blogs, short for weblogs, are perhaps the most traditional of the technologies and are essentially websites that can be dynamically and regularly updated. Wikis are information-distribution sites that exist through the collective efforts of many users. Wikis are intended to efficiently harness the collective knowledge of all willing participants. In general on a wiki, all users can generate original content and edit or remove published content. The core concept of the wiki is that all changes can be made, or undone, quickly. Social networking sites represent the ability of internet technologies to connect users and provide a platform that enables these connections.

Blogs

Blogs are simple websites that are largely defined by the fact that they are updated easily and regu-

larly. Blogs are inherently flexible and can be used for a variety of purposes, ranging from knowledge management initiatives (Sultan, 2013) to customer engagement tools (Brodie, Ilic, Juric, & Hollebeek, 2013) or potential sources of business intelligence (Chau & Xu, 2012). In fact, blogs have long been challenging traditional media outlets for the attention of many online users (Singh, Veron-Jackson, & Cullinane, 2008).

Blogs can serve as rallying points for people of similar interests, such as consumer advocates at the Consumerist (www.consumerist.com), and organizations can also offer their own blogs as a platform on which to interact directly with customers. Blogs can serve as a platform to gain the attention of an organization (Roberts & Dinger, 2016), as they not only enable individuals to publically voice their own concerns, but entire communities can form regarding a common cause. For example, in 2005, a writer for BusinessWeek chronicled his complaints with Dell on his own personal blog, called Dell Hell (Jarvis, 2007). Eventually, he penned an open letter to Michael Dell and challenged him to respond to the public complaints and concerns of bloggers. The following year, Dell capitalized on the chance to positively interact with their customers by creating their own blog (Fournier & Avery, 2011).

Within-firm blogs offer a platform for individual employees to express themselves inside the firm. These repositories can be used to store thoughts or voice opinions, and as such, internal blogs can be used as a knowledge repository and to enhance knowledge sharing (Baxter & Connolly, 2013). Executives have been regularly using internal blogs to publicize statements within firms and connect with their own employees (Gaines-Ross, 2013). Firms and CEOs can use a public blog in order to provide a 'face' for the organization (Vidgen, Mark Sims, & Powell, 2013). The publication of a blog enables the firm to interface directly with consumers. By allowing customers to interact directly with the firm, the organization may seem more human and down-to-earth (Singh et al., 2008). While the blog can be used for impression management, it can also be

used to gauge consumer reactions to changes or investigate the potential for new products. For instance, Facebook makes public announcements on their blog and updates users on potential changes to Facebook (blog.facebook.com).

Wikis

Wikis are a type of technology that allows many users to combine their collective knowledge (Gaines-Ross, 2013). The wiki is a type of technology that also embodies a specific mindset towards the accumulation of knowledge. Wikis are designed such that participants can quickly and easily create new wiki pages, edit existing wiki pages, and trim unnecessary wiki pages. Wikis offer the ability for many users to converge on a given topic. As such, wikis represent an excellent technological platform for knowledge generation and can be harnessed to inspire innovations and growth (Biasutti & Heba, 2012). Wiki technology enables users to search for information, link other articles, author new articles, and tag articles (McAfee, 2006). Furthermore, wikis can use extensions to enhance user ability to find related content and set up signals which notify users of new content (McAfee, 2006).

A popular source of online information, Wikipedia hosts over 5.1 million articles in English alone. However, the collaborative nature of public wikis raises concern about the validity of information contained in such a source (Reavley et al., 2012). Therefore, a number of checks are implemented to insure the validity of contributions to a given wiki topic. A common wiki tenet is to make it easy to correct mistakes. Changes are tracked and edits are easily undone. This makes it a simple task to undo vandalism. Firms have the opportunity to derive value from the collective of the public that participates in wikis. Wikis can form around any given subject. For example, users of the Linux-based operating system Ubuntu operate a wiki to assist all Ubuntu users (wiki.ubuntu.com).

Firms have the opportunity to harness the power of their consumers by creating and driving

wikis that feature the firm's products. By allowing consumers to create content revolving around the firm's products, the firm is both developing the core consumer base in a positive manner and enabling the creation of additional value for any consumer that can benefit from this knowledge and experience. For instance, fans of Marvel properties have created the Marvel Database (marvel.wikia.com), which hosts over 150,000 articles created and moderated by the fan community.

Internal wikis can be applied to a number of possibilities. Wikis offer value as tools for collaborative knowledge management (Gaines-Ross, 2013). The wiki becomes a repository of knowledge that users can improve over time. For example, one report suggests that the U.S. Government leverages wikis in a variety of ways, including an Army-based wiki on Afghanistan, an intelligence wiki full of non-classified information for government personnel (Intellipedia), and a wiki for diplomats (Diplopedia) (Bell, 2009). Wikis are relatively easy to set up and modify, which makes them ideal for projects and routine use. Wikis can be created at the beginning of a project and then modified according to project progress. Alan Mansfield, a small business owner, estimates that using wikis to manage projects cuts down time spent on each project by 25 percent (Miller, 2006). In running his literary agency, Mansfield uses wikis to "store drafts, e-mails, proposals, contracts, contacts, and anything else to do with the project" (Miller, 2006).

Social Network Sites

Social network sites (SNS) use internet-enabled technologies to allow users to form or maintain social connections. Boyd and Ellison define social networks as "web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system" (2007 p 211). The core factors driving SNS are the platforms on which many users can

W

engage and interact with one another. SNS have become so extensive that firms are having trouble with employees who insist on accessing social networking sites during regular working hours (Andreassen, Torsheim, & Pallesen, 2014).

While firms may view social networking as a distraction to employees, firms can seek to engage with social networking software in a value-generating manner. Many companies leverage social networking software internally in order to facilitate connections and exchanges between employees (Leonardi, Huysman, & Steinfield, 2013) and enhance knowledge sharing (Ellison, Gibbs, & Weber, 2014). Social networks also facilitate connecting potential participants for distributed innovation processes (Lee, Olson, & Trimi, 2012). As recruitment tools, social networks present a valuable tool that can be leveraged by recruiters to more thoroughly assess potential recruits (Davison, Bing, Kluemper, & Roth, 2016). Organizations can also use social networks and social media to engage in direct market research (Chen et al., 2012; Fan & Gordon, 2014). Also, social networks enable firms to create higher levels of customer engagement through positive discourse with customers (Sashi, 2012).

A FRAMEWORK FOR WEB 2.0 INITIATIVES

This framework attempts to simplify and direct Web 2.0 initiatives. Due to the broad range of potential Web 2.0 initiatives, we propose a framework for understanding the value generated from these initiatives.

Value Derived within the Firm

This part of the framework addresses the ability of the firm to generate value through Web 2.0 initiatives. These applications may take a variety of forms, but the focus is on the benefits of the internal applications of the Web 2.0 applications. These applications may take form in terms of

knowledge management initiatives (Gaines-Ross, 2013; Sultan, 2013), project management efforts (Miller, 2006), and social networks that connect employees (Leonardi et al., 2013). Firms must understand the type of benefit they intend to achieve before installing Web 2.0 technologies. The application of multiple Web 2.0 endeavors allows for firms to integrate across technology, thus potentially giving rise to super-additive value due to the complex interactions between multiple Web 2.0 platforms (see Figure 1).

Value Derived from External Sources

The firm should consider how to derive value from Web 2.0 instances that exist in the public space. The firm should evaluate all potential sources of access to these instances. Once the sources are identified, the firm can approach the issue of deriving value from these websites. For instance, firms can leverage social network sites to evaluate job applicants or to actively recruit individuals (Davison et al., 2016). Firms can also capitalize on externally-run blogs in order to understand the mindset and concerns of customers, as external sites provide access to the unfiltered complaints of customers (Fournier & Avery, 2011). Due to the open and simple nature of Web 2.0 technologies, many users are participants on multiple platforms. Furthermore, users, and Web 2.0-savvy businesses, form connections between multiple Web 2.0 initiatives. For instance, Facebook enables Instagram users to link their account to their Facebook account and post content to both Instagram and Facebook simultaneously. The challenge for firms is to identify potential sources of value and to effectively funnel value from those sources into the firm (see Figure 2).

Value Derived from the Interaction Between the Firm and Public

Firms should evaluate how to generate value from dynamic interactions with their customers or other public sources. This proposition deals

Figure 1. Value derived within the firm

Figure 2. Value derived from external sources

with two fronts: social and technical. The social aspect of this interaction deals with the actual exchange between firm and public. For instance, Dell responded to customer complaint blogs directly (Jarvis, 2007). Beyond interacting directly with customers and other external parties, a firm may choose to create a platform to facilitate this interaction. For instance, Dell chose to publish a blog (a technical issue) for the purpose of interacting with customers (a social issue) (Fournier & Avery, 2011; Jarvis, 2007). This suggests that firms must first understand and engage Web 2.0 technologies from a technical perspective before progressing to capitalizing on potential social interactions via firm-driven technologies.

Furthermore, firms can capitalize on direct involvement with customers and third parties by creating a platform to drive distributed innovation (Lee et al., 2012). Many design initiatives focus

on distributing design and innovation processes within the firm. However, firms can leverage these technologies and allow customers to become involved in the creation processes (Frow, Nenonen, Payne, & Storbacka, 2015). In doing so, firms can engage in dynamic value generation in conjunction with customers and third parties. Firms can seek to integrate technologies within the firm and with external sources in order to reach out and provide a platform for dynamic social interactions and distributed innovation processes (see Figure 3).

Value Derived from Innovative Business Models

Firms must stay current amidst the constant change of business models. For instance, firms are attempting to develop retail environments within online virtual worlds (Frow et al., 2015).

Figure 3. Value derived from the interaction between the firm and public

Furthermore, firms may consider how to leverage social media and mobile applications to advance firm goals and create additional value for consumers and the firm (Aksoy et al., 2013). Online firms may focus on implementing aspects of Web 2.0 technologies into their existing business models. For instance, online retailing environments may enable individual sellers to connect their web stores, thus leading to a virtual mall for online shoppers (Stephen & Toubia, 2010). Firms, both online and traditional, must stay on top potential changes to their business model in order to be competitive in this fast-paced environment.

Risks Posed by Web 2.0 Initiatives

In seeking to gain value from Web 2.0 endeavors, firms must not ignore the risks associated with these technologies. Primarily, firms must control their exposure regarding information technology security. While these technologies inherently connect individuals within the firm and may connect the firm to outsiders, firms must maintain tight security standards in order to prevent unauthorized access or the introduction and spread of harmful computer viruses. Similarly, firms should be wary of potentially unreliable information available from external sources. The potential for bad information in online settings is always a concern and is particularly relevant regarding wikis (Reavley et al., 2012), however, recent trends have tilted towards analytical study of large data sets derived from social media, which should iron out small fluctuations in data accuracy (Chen et al., 2012; Fan & Gordon, 2014).

CONCLUSION

Web 2.0 technologies have not only changed the landscape of the internet, but continue to create a dynamic and changing competitive environment for many firms. Firms that aggressively implement Web 2.0 and social media technologies may

successfully develop competencies that create additional value and drive competitive advantage.

KEY TERMS AND DEFINITIONS

Blogs: Short for ‘weblogs,’ blogs are simple, content-driven sites that are updated regularly.

Distributed Contributions: The practice of leveraging the willing participation of users.

Dynamic Content: Internet content that can be modified and uploaded quickly which keeps users ‘up-to-the-minute.’

Rich Media: Media, particularly images, video and sound, conveyed via internet technologies that provides a deeper user experience than simple text.

Social Networking Elements: Web 2.0 applications embedded in web sites that enable users to uniquely identify and form connections with one another.

Social Networking Sites (SNS): Web-based platforms which enable many individuals to create individual profiles, find and connect with other users.

Web 2.0: An umbrella term that refers to an assortment of advances in internet technologies, marked by increases in rich media, dynamic content, social networking elements, and distributed contributions.

Wikis: Content-driven sites which are editable by all participants and focus on harnessing the collective knowledge of all users.

Search Engine Optimization

Dimitrios Giomelakis

Aristotle University of Thessaloniki, Greece

Andreas A. Veglis

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The extensive range of information resources and services is certainly one of the most important features of the Internet while at the same time, web search is considered as a crucial application for managing the massive volumes of distributed web content. Beyond argument, search engines have made an enormous contribution to the web by making the process of finding information online a very quick and easy process. Today, major search engines are considered to be the most common and trusted tool or service to retrieve information from the Internet (Spink & Xu, 2000). Also, they are the primary method used for navigation for hundreds of millions of users worldwide and one of the most common online activities (Purcell, 2011; Purcell, Brenner, & Rainie, 2012). The majority of Internet traffic depends largely on them (Safran, 2013) and thus, web search is one of the best sources of traffic for any website. However, it is true that the vast majority of all search traffic comes from the first or the first pages of search results as users usually focus on the top ranks.

There are two ways an online user – customer will find a business website via a search engine: through a pay-per-click campaign (PPC) or through an organic result listing that is based essentially on what is called Search Engine Optimization or briefly, SEO. The latter can be defined as the process of affecting - improving the visibility of a website (or a web page) so that it ranks well for particular keywords in a search engine's "natural" or "organic" (un-paid) search results (Ledford,

2009; Potts, 2007). Generally, the earlier, and more frequently a site appears in the search engine results page, the more visitors it will receive from the search traffic. In other words, it is a set of techniques that take into account the evaluation criteria of search engines regarding website content and structure (Giomelakis & Veglis, 2015a).

There have been plenty studies regarding online users' click behavior on search engine results pages. According to the results, 90 percent of search engine users never read beyond the third page of search results (iProspect, 2006). Also, the top listing in Google's organic search results receives 32.5 percent of the traffic, compared to 17.6 percent for the second and 11.4 percent for the third position. Finally, websites listed on the first page in Google's results generate 92 percent of all traffic from an average search (Chitika, 2013). From all the above, it is evident that if a website is not in the first search results page or even worse is absent from the top 30, it has almost no chance of being read by a user (Clay, 2006). As a consequence, and while more and more websites are indexed by search engines and compete one another to ensure their own market share, it is clear that factors as the highest ranking and top of the results page become increasingly essential for businesses of all kinds (Enge, Spencer, & Stricchiola, 2015; Giomelakis & Veglis, 2015a).

This chapter provides an overview of Search Engine Optimization, with a focus on its different characteristics as well its history and how it has evolved over the years. In order to give a better understanding of the importance of SEO in the

current state of the Internet and in information search, basic knowledge of how search engines operate along with their recent updates are also provided.

BACKGROUND

Search engines are software that catalogs the World Wide Web and provides search using keywords into their vast databases containing full-text indexes of web pages. Users actually search this database of retrieved web pages, not the World Wide Web itself. As a consequence, they manage to take rapid results something that would be impossible if engines were trying to search billions of pages on the web in real time (Veglis, Pomportsis, & Avraam, 2004). When users click on search results they retrieve the current version of a web page. It is worth mentioning that search engines consist of three parts: the web crawler or spider, the indexer and also the query processor (Mudgil, Sharma, & Gupta, 2013). The crawler systematically browses the World Wide Web, looks at every URL (Uniform Resource Locator) collecting keywords and phrases on each page, which are then included in a massive database. The crawler is also responsible for keeping indexed pages up to date (Ledford, 2009). Search engines start with a set of very high quality sites and then visit the links on each page (of those sites) to discover other web pages. This complex process repeats over and over again until the crawling is complete. Through links, web crawlers (i.e. automated robots) can reach the many trillions of interconnected documents (Enge, Spencer, & Stricchiola, 2015).

Search engines use algorithms so as to find and collect information about web pages. Generally, a search algorithm can be characterized as a problem-solving procedure that takes the problem (i.e. the users' word or phrase), sifts through a vast database of cataloged keywords with their URLs, and then returns a listing of best-matching web pages according to the search criteria. Search results (i.e. page ranking) usually depend on the

perceived quality-importance of the page (quality score - links from other sites) conforming to the algorithm that's being used as well as on relevance (relevant terms/links) and several other factors such as frequency of keywords, location, age or click-through rates (Ledford 2009; Enge, Spencer, & Stricchiola, 2015). It is worth mentioning that in the case of Google, the famous PageRank (one of its oldest algorithms) is a quality metric used in ranking (one out of many) that measures the importance of web pages by counting the number and quality of links to a page (Page, Sergey, Rajeev, & Winograd, 1998; Grappone & Couzin 2008). PageRank (PR) is a numerical measurement (0–10, the higher the better) and in the past it was one of the most important factors. Google has continuously improved the way it uses links to impact rankings (one reason is to deal with link spam), and its current algorithm is not based on PR as it was originally defined (Enge, Spencer, & Stricchiola, 2015). However, it still has some value in SEO (Grappone and Couzin 2008; Slegg 2013; Giomelakis & Veglis, 2015b). Also, it is true that PR had become an obsession for many SEO workers worrying about their numbers and examining closely the quality of every new link. The last Pagerank update was in December 2013 and on April 15, 2016 the search engine has officially shut down the PageRank data to public (Southern, 2016; Schwartz 2016). In brief, search algorithms can be classified into three broad categories: on-page algorithms that measure on-page factors looking at the elements of every page (e.g. keywords in content or meta tags), whole-site algorithms that focus on the relationship of site elements (e.g. anchor text, linking between pages or architecture of pages) and finally, off-site algorithms that explore the links between the websites. All these three types are generally part of a larger algorithm (Ledford, 2009).

Search Engines have evolved dramatically over time and they constantly "crawl" the web to update their databases with new information. According to statistics, Google is the world's most popular search engine having the vast majority

(over 2/3) of the global search engine market followed by Bing, Yahoo and Baidu, China's most popular search engine (Netmarketshare, 2016). In a comScore survey (2015) data showed that Google sites led the U.S. explicit core search market with 64.5 percent market share, followed by Microsoft sites with 19.8 percent and Yahoo! sites with 12.8 percent.

HISTORY OF SEO

SEO constitutes a part of Search Engine Marketing (SEM) and it is considered one of the leading and most influential activities in the field of online marketing, hence there is a wealth of information and tools designed to train and support the community (Potts, 2007; Nigro, Balduzzi, Cuesta, & Cisaró, 2012). Historically, the actual phrase "Search Engine Optimization" was possibly first coined in 1997 by an unknown person. Search guru Danny Sullivan found for the first time the term used in May 1997 in a meta tag on his website, Search Engine Watch. However, it is quite possible that it was used before that. Sullivan acknowledges Bruce Clay as one of the first people in the industry to popularize the term (Sullivan, 2004; Dover, 2011).

SEO has always been associated with the influence of search engine results and its creation is rationally connected with the creation of the first search engines in the early-mid 90's. Danny Dover describes (2011) that early SEO experts used to take advantage of alphabetical ("AAA", "1ForU") and chronological (submit websites at certain times) order to get to the top of rankings. Since then, things have changed considerably. Search engines improved using more complicated algorithms and at the same time, SEO became a more profitable business. Over time, site owners started to identify the worth of having their websites highly ranked and visible in online search results. They also noticed that the higher their website ranked, the more people would click on their content. From a simple URL submis-

sion initially and use of unsophisticated tactics, companies started to implement strategies such as keywords insertion, link building (process of obtaining hyperlinks from other websites), and recently social media utilization.

From the early days of search engines until today many SEO users have attempted to deceive search engines in order to artificially improve their visibility. That is usually called as "black-hat SEO" and pertains to the use of strategies or tactics (e.g. excessive use of keywords, hidden text or pages) that are used to get higher rankings in an unethical manner, doesn't obey search engines guidelines for webmasters or involve deception. In general, it is a practice that violates the search engines' terms of service and possibly results in a website being banned from a search engine and affiliate sites (Grappone & Couzin 2008; Ledford 2009). A remarkable example of penalizing was Google removal of BMW Germany and Ricoh Germany for using misleading tactics in 2006 (Cutts, 2006). As stated, search engines have evolved tremendously in recent years and one of the most basic reasons that their algorithms are in a constant change is due to the need to address "Black Hat SEO" and provide the best possible results. Thus, they developed more complex ranking algorithms, considering additional factors that were more difficult for webmasters to manipulate.

SEO CHARACTERISTICS

There are definitely myths about search engines. For example, that attaining a top spot in the organic, natural results requires actually paying Google and other search sites. On the contrary, a high position in search results requires actually worthy content coupled with time, effort, and skill (Potts, 2007). SEO can be applied to many different websites to some degree and can target different types of search, including image - video search, local, news or academic search (Beel, Gipp, & Wilde, 2010; Giomelakis & Veglis, 2015b; Wikipedia, 2016). Arguably, it is very closely connected to

e-Commerce websites (Malaga, 2007). According to a relevant study, 89 percent of consumers turn to search engines to find information on products, services or businesses before making purchases (Fleishman-Hillard & Harris Interactive, 2012). Given that it takes into account how search engines work and the actual terms that people search for, there are several factors that affect SEO but unfortunately, there is no magic recipe for the first page and certainly no guaranteed results. By contrast, there is a variety of things to consider that in conjunction can bring good results. Some of them can directly affect SEO while others can have an indirect impact on search rank. Everything has its value and Google, Bing or other search engines use them to evaluate and rank web pages in their results. Although there are differences in the ways various search engines work, the basic rules remain similar and a well-planned SEO strategy can usually bring good results in all major search engines (Giomelakis & Veglis, 2015a).

SEO strategies can be divided into four main categories: keyword research/selection, search engine indexing, on-page optimization and off-page optimization (Malaga, 2008). *On-page optimization* refers to the management of all factors related directly to someone's website (content – appropriate keywords, architecture and internal link structure as well as html elements). More specifically, this category contains among others, page titles (or HTML titles tag that usually appear in search results), on-page headlines, description of web pages (or meta description tag) and URL's. Using main, appropriate words/phrases that people often use in their searches in all the above elements is crucial to SEO. However, it should be noted that the use of keywords to a great extent in the actual content of a web page is by all means not a key requirement. In contrast, it is effective when this happens naturally without boring the readers. Besides, keyword stuffing (i.e. the practice of overloading a web page's content with keywords) can bring unpleasant results to a website (Giomelakis & Veglis, 2015a). Further-

more, as mobile devices become more prevalent in daily life, a good user experience across all devices (desktop, tablet or smartphone) has become a significant consideration in SEO strategy (mobile SEO). Google has updated its algorithm in this direction (it took the name "Mobilegeddon") given that in many countries around the world including the US and Japan, more searches take place on mobile devices than on computers (Makino, Jung, & Phan, 2015; Dischler, 2015).

Examples of SEO Practices

1. Page titles/headlines
 - a. World Cup 2014: Brazil humiliated by Germany 7-1 in semi-final / Novak Djokovic beats Roger Federer in epic Wimbledon 2014 men's final (SEO-Friendly)
 - b. Germany's triumph in the semi-final / Djoko did it again! (Non-SEO Friendly)
2. Url's
 - www.newsandseo.com/2014/seo-best-practices-for-structuring-urls.html (SEO-Friendly)
 - www.newsandseo.com/2014/how-to-create-seo-friendly-urls.html (SEO-Friendly)
 - www.newsandseo.com/2014/new/item.aspx?itemid=3051.html (Non-SEO Friendly)
 - www.newsandseo.com/2014/forum/viewtopic/m-159327.html (Non-SEO Friendly)
3. Different titles/headlines

This practice is used by several news organizations (e.g. BBC News, Guardian, Huffington Post or New York Times) and the most common is the different headlines between home page or other Web site indexes and the story page itself (see figure 1). The latter that appears in search results, is usually more specific including more keywords for the topic.

Figure 1. The dual headline system in BBC news

Regarding *off-page optimization*, it includes all the efforts made away from someone's website like link building or social signal strategy. Links from other websites (called backlinks or inbound links) have great importance, serve as votes for the value and are a basic requirement for a web page to be found both from search engines and online searchers. In addition, it is highly important for inbound links to be qualitative, coming from well-known, trusted websites in order to give much more value and better evaluation. There are many different ways to gain inbound links such as articles/domain submission to directories (e.g. Dmoz), forum, blogs, and news aggregators as well as building relationships and links exchange with other websites. It is true that for a website with quality content, it is usually a matter of time until it gains many natural and qualitative backlinks. However, not only inbound links but also external links that lead to other relevant web pages (preferably credible and high-ranking sites) can contribute positively especially if a website is new (Giomelakis & Veglis, 2015a).

SEO, SOCIAL MEDIA AND CONTENT

The development of the World Wide Web (Web 2.0) over the last decade has affected and brought significant changes in web content such as user-generated content and social web. Furthermore, search technology itself evolved over the last years with the growth of contemporary search engines something that has arguably affected SEO. Nowadays, the optimization for search engines is not anymore only about link-building and keywords. Social media and social signals (such as Facebook Shares/likes) have increasingly become one of the many factors search engines take seriously into account. In order to enhance their perfect reach, many search engines incorporate information from Web 2.0 services into their searchable indexes (Zimmer, 2008). For instance, active Facebook profile pages have many ranking possibilities for branded, subject-based and personal name-based queries at Google results. Also, due to Twitter's domain authority, its profile pages also rank highly for relevant searches. Results from Twit-

ter can be used for queries where real-time data are helpful (Dover, 2011). Regarding Google+, its characteristics make it a far superior platform for SEO and sharing content on it can possibly influence search rankings in significant ways (Shepard, 2013). In this context, recent studies from Searchmetrics (2013) and Moz's experts (Peters, 2013) confirmed how important social media signals are to SEO ranking, especially Google +1s. Social signals, in general, have a positive impact on websites and are considered as the new link building metric as search engines increasingly search for social signals to help the ranking of pages (Rayson, 2013; Frasco, 2013). The more referrals someone has across the web, the more search engine spiders notice and categorize their content (Ehrlich, 2013). Social media and SEO do overlap, and the former can contribute to the total organic success of websites in several ways (Pascale, 2014).

Today, recent algorithm changes from search engines especially in Google (e.g. Penguin, Panda, and Hummingbird) have added more value to quality as well as content marketing that many experts have called it as the new SEO (DeMers, 2013). For example, the change of Panda algorithm (February 2011) was made in order to eliminate low-quality websites in favor of those with frequently updated, in-depth content. Also, Google Penguin (April 2012) was the response to "Black-hat" SEO and web spam and finally Hummingbird (late 2013) added the contextual search, a way to interpret content by looking at the relationship between terms (Rampton & DeMers, 2014). The world of SEO is constantly evolving and thus, SEO workers have to be always up to date on new developments and also utilize useful tools and services for their work. Tools such as Google Analytics (the most widely known web analytics package), Google PageSpeed Insights (analyzes the performance of a web page providing information on how to improve the load time), Google Search Console (previously Google Webmaster Tools that enable webmasters to monitor and maintain their presence in search results), Google Trends (a tool to iden-

tify "hot" topics), SEMrush (software for online marketing) or finally MozBar (for the page and domain authority of a website) are very popular in SEO industry. It is crucial to understand that SEO is not only about engines but also making someone's website (and its content) user-friendly and better for people. The content is still the most important thing for any website and this has to be reliable and interesting. Even search engines look now for unique, qualitative and useful content that will satisfy and motivate readers to share it through social networks, blog posts or forums. In spite of how good is SEO, it is not likely for any website with useless content to get ranked well in the long term because no one is ever going to visit or look for it. Besides, Google and other search engines got much smarter and can distinguish between content with real value and content that exists only for SEO purposes.

FUTURE RESEARCH DIRECTIONS

Beyond argument, there are several important aspects in this field that require further study. For instance, the increasing involvement of social media in SEO strategy is an area of research that has to be studied more in order to better clarify the relation between them. And that's because there is a strong indication that social networks and social media, in general, will continue to increase their significance and presence in the internet population. It is true that web search is increasingly becoming more personalized and user influenced. For many years, SEO and search results were all about keywords and link building. Nowadays, things are changed, the search results are arguably better and the search experience is much more advanced. SEO experts need to take the audience, their interests, user experience or what device they are using more into account when developing their strategies. All the above are issues that deserve more careful attention in future research because these are elements intimately related with search engines. In this context

and as the web ecosystem evolves, the so-called mobile, local or vertical search-SEO has grown considerably gaining significant attention from field experts. Also, we would say that the mobile landscape has evolved to such an extent that it has become a completely unique (mobile-first) search environment. All these new types of SEO along with the opportunities they offer in online industry are areas that need to be addressed in future studies.

CONCLUSION

Undeniably, search engines have come a long way since their appearance in the early 90's. In this context, SEO grew out of the development of search engines and the World Wide Web. As the years pass, there is no question that search engines will continue to evolve their algorithms and make improvements in their ability to crawl and index new types of content such as multimedia or data coming from social media. Over time, there have been fundamental shifts in the SEO landscape and field experts see a shift away from traditional ranking factors to deeper analysis and factors such as quality, multi-form content and social signals (DeMers, 2013). Within this progress, social media have increasingly become one of the many factors search engines take into account and content is still the king (Zimmer, 2008; Dover, 2011).

It might be thought that SEO will always have a place in a web strategy as long as Google and other search engines continue to drive a great amount of traffic on the Internet. The tactics involved in optimization may change, but the need will always remain. It is evident that every business that has a web presence (or wants to get clients from the web) would be wise to think about a SEO strategy as well as the potential it creates in order to increase or maintain its position within the search results. Implementing SEO into a website is becoming more and more necessary in today's digitalized world. Given that people will always be on a quest for information, and given the market-

ing imperative to get your information seen and keep ahead of the competition, companies will continue to figure out ways to use SEO-related techniques for higher rankings. The good use of SEO certainly does not guarantee high traffic and top rank. Nevertheless, an effective strategy can play its role by helping companies to obtain the best results and take advantage of the benefits provided through the utilization of search engines and web search in general.

KEY TERMS AND DEFINITIONS

Click-Through Rate (CTR): The ratio of users who click on a specific link compared to the number of total users who view an email, a web page or an advertisement. It is used to measure the success of an advertisement campaign. For example, if an advertisement had 10 clicks and 1000 impressions (number of times it was served), the CTR would be 10% (clicks / impressions x 100).

Local Seo: The optimization process that focuses on results that are relevant to a user based on its current location.

Organic Results: Also called «natural» or un-paid. The results that appear because of their relevance to the search terms.

Social Signals: A kind of recommendations through social media. Social signals are the Facebook shares or likes, the tweets, Google +1s, pins or some other way of social media bookmarking or sharing.

User-Generated Content (UGC): Any form of digital content such as images, video, status updates or blogs that is produced and shared by users of an online service or website, often made available via social media websites.

Vertical Search: The search accessibility of specific segments and formats of online content. Vertical search services focus on specific topics such as news, restaurants or products. Google provides also vertical search such as Google news or Google images.

Toward Trustworthy Web Services Coordination

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

Many Web-based companies such as amazon.com, yahoo.com and twitter.com have been offering Web services to their partners and customers. Through such Web services, new value-added services have been provided and hence higher revenues have been generated. Essentially, the Web services technology is transforming the World Wide Web from a predominantly publishing platform to a programmable platform, which undoubtedly will make it easier to conduct business online, and enable automated business-to-business communications (Papazoglou, 2003; Zhao et al., 2008). The Web services technology is particularly useful for Application Service Providers that offer various on-demand services and software-as-a-service (SAAS) to their customers (Chakrabarty, 2007). Such service-oriented computing is attractive to many businesses because they can save valuable resources and money by avoiding installing and maintaining sophisticated enterprise software on-site. Furthermore, most of business interactions are transactional, which require well-defined standardized coordination support. To meet this requirement, a number of specifications have been proposed and rectified by OASIS (Feingold & Jeyaraman, 2009; Little & Wilkinson, 2009; Freund & Little, 2009).

Inevitably, the dependability requirement of these Web services has been increasing because of the key role they play in e-businesses. One of the most well-known approaches to enhancing the trustworthiness of Web services coordination is Byzantine fault tolerance (BFT) (Zhao, 2014). The BFT technique employs space redundancy

(i.e., replication) and a replication algorithm that can tolerate malicious faults (often referred to as Byzantine fault) (Lamport et al., 1982; Castro & Liskov, 2002).

In this article, we present an overview of our recent works on enhancing the trustworthiness of Web services coordination for business activities and transactions. The approach is based on what we call application-aware Byzantine fault tolerance. We argue that it is impractical to apply general-purpose Byzantine fault tolerance algorithms for such systems in a straightforward manner. Instead, by exploiting the application semantics, much lighter weight solutions can be designed to enhance intrusion tolerance, and hence the trustworthiness of systems that require Web services coordination.

BACKGROUND

Web services interactions are becoming more and more complex in structure and relationships. More complex means we need longer time to execute them, because of business latencies and user interactions. The Web Services Coordination specification (WS-Coordination) (Feingold & Jeyaraman, 2009) describes an extensible framework for plugging in protocols that coordinate the actions of Web services applications. Such coordination protocols can be used to support a variety of business applications, including those that require strict consistency and those that require agreement of a proper subset of the participants. The framework enables a Web service to create a context needed to propagate an activity to other

Web services and to register for a particular coordination protocol.

There are two types of business transactions. One follows the traditional atomic transaction semantics, and the other is referred to as business activities, which implies that the atomicity property may be relaxed. The former is suitable for short transactions that require strong atomicity, such as a fund transfer transaction. The latter is more suitable long running transactions, such as those used in supply chain management. Based on WS-Coordination, two specifications, namely Web Service Atomic Transaction (WS-AtomicTransaction) (Little & Wilkinson, 2009) and Web Service Business Activity (WS-BusinessActivity) (Freund & Little, 2009), were standardized by OASIS to address the coordination needs for common types of business transactions.

Web Services Atomic Transactions

The Web Services Atomic Transactions specification defines a coordination framework for Web services atomic transactions. In a distributed atomic transaction, all participants must reach the same final agreement as to whether the transaction has succeeded or not. This is ensured by the coordination mechanisms specified in WS-AtomicTransaction. In WS-AtomicTransaction, there are three actors for each transaction: Completion Initiator, Coordinator and Participants. Each provides a different set of services for the atomic transaction, and they interact with each other via two protocols, the Completion Protocol and the Two-Phase Commit Protocol (Gray & Reuter, 1993) (Tanenbaum & Steen, 2002).

The completion initiator is responsible to start and terminate a transaction. It also provides the Completion Initiator Service so that the coordinator can inform it the final outcome of the transaction, as part of the completion protocol. The coordinator provides the following services:

- **Activation Service:** At the beginning of a transaction, the initiator invokes the

Activation Service for creating a coordinator object, which will generate a new coordination context for the transaction and return it to the initiator. The coordination context contains a unique transaction identifier and an endpoint reference for the Registration Service. This coordination context will be included in every request messages within the transaction boundary.

- **Registration Service:** The participants and the completion initiator use this service to register their endpoint references for other associated participant-side services. Later these endpoint references will be used by the coordinator to contact the participants during the two-phase commit.
- **Coordinator Service:** When a participant gets a Prepare request from the coordinator, it places its vote by invoking the coordinator service. The participants also use this service to notify the coordinator their acknowledgments to the commit/abort request. The participants obtain the endpoint reference of the Coordinator Service during the registration step.
- **Completion Service:** The initiator invokes this service to notify the coordinator to start a distributed commit. The Completion service, together with the Completion Initiator service on the participant side, implements the WS-AtomicTransaction completion protocol. The endpoint reference of the Completion Service is returned to the initiator during the registration step.

The participant provides the Participant Service, which allows the coordinator to solicit votes from, and to send the transaction outcome to the participants according to the two-phase commit protocol.

The Completion Protocol is used by the completion initiator to initiate the atomic termination of a transaction. When the initiator decides that it is time to commit the transaction, it sends a Commit request to the coordinator. The coordinator

will then launch an instance of the Two-Phase Commit (2PC) protocol to carry out the coordination for atomic commitment of the transaction. When the 2PC completes, the coordinator notifies the initiator the outcome of the transaction (i.e., Committed or Aborted). If the request from the initiator is Rollback instead, the coordinator will abort the transaction directly.

The 2PC Protocol is used by the coordinator and participants to guarantee atomic commitment of a transaction, and it executes in two phases. During the first phase, i.e., the prepare phase, the coordinator sends a Commit request to all registered participants soliciting their votes. When the coordinator receives votes from all participants, or a timeout has occurred, it starts the second phase, i.e., the commit phase, to notify the participants the outcome of the transaction.

2PC has two variants used for different resources, Volatile 2PC and Durable 2PC. Volatile 2PC is used for volatile resources such as caches and Durable 2PC focuses on durable resources like a database. Participants must register in an appropriate protocol before the termination of the transaction. A participant can register in more than one protocol. Upon receiving a Commit request from the initiator in the completion protocol, the coordinator begins the prepare phase first for every participant who has registered in the Volatile 2PC protocol by sending a Prepare request to them before it begins the prepare phase for Durable 2PC. The participant that gets the request must respond with a Prepared, Aborted or ReadOnly message based on its own decision. During this period, other participants can continuously register with the coordinator for Durable 2PC, but the registration progress has to be done by the coordinator before the start of the first phase for durable resources. After the prepare phase for Volatile 2PC, the coordinator begins to take care of the prepare phase for Durable 2PC participants. Same as the prepare phase of Volatile 2PC, all participants in the Durable 2PC protocol have to

respond appropriately before the protocol advances to the second phase, in which the coordinator will issue the Commit requests to all participants for both Volatile and Durable 2PC protocols if all participants have provided positive feedbacks. If there are any negative votes, even if only one, the coordinator has to abort the transaction. After the participants get a Commit notification, they will commit the transaction and send the Committed acknowledgement back to the coordinator.

Figure 1 shows an example of a Web services atomic transaction for a travel reservation coordinated by WS-AtomicTransaction. In this example, a client contacts a Travel Agent to make travel arrangement. The Agent, which acts as the completion initiator, is responsible to make flight and hotel reservations in the context of an atomic distributed transaction, on behalf of the client. We assume that the Agent relies on a Flight reservation Web service and a Hotel reservation Web service, for booking a plane ticket and a hotel room for the traveler.

To begin this transaction, the client sends a request to the initiator (step 1). The initiator invokes the Activation Service on the Coordinator. This will create a unique coordination context for the transaction (step 2). This context contains the Endpoint Reference for the Registration Service. After the Activation step, the initiator gets the reply back with the transaction context (step 3). In next step, the initiator registers the Completion Initiator Service with the coordinator so that the coordinator could inform the initiator after it obtains the outcome of the transaction (steps 4 and 5). Now the booking service offered by the initiator carries out the reservations for the plane ticket and a hotel room (steps 6 and 10). The flight and hotel booking Web services must register their participant endpoint references with the coordinator (steps 7 & 8 and 11 & 12). After the registration step, these services will send their responses for the reservation requests (steps 9 and 13). Subsequently, the initiator asks the Comple-

Figure 1. An example Web services atomic transaction

tion Service to commit the transaction (steps 15 – 17). Finally, the Travel Agent sends the result back to the client (step 18).

Web Services Business Activities

WS-BusinessActivity differs from WS-Atomic-Transaction in that it focuses on the coordination of long running business activities where the atomic transaction model is not appropriate. WS-BusinessActivity is also built on top of the WS-Coordination framework. The WS-Business-Activity specification describes two coordination types, Atomic-Outcome and Mixed-Outcome, and two coordination protocols, Business-Agreement-with-Participant-Completion and Business-Agreement-with-Coordinator-Completion. Either protocol can be used with either coordination type. If the Atomic-Outcome Coordination type is used, all participants must reach an agreement

about the activity outcome (i.e., either to close or to compensate). If the Mixed-Outcome coordination type is used, some participants may be directed to close while others to compensate. All WS-BusinessActivity frameworks must implement the Atomic-Outcome coordination type.

In a WS-BusinessActivity framework, a participant registers either one of the two protocols, which are managed by the coordinator of the business activity. The only difference between the two protocols is that the Business-Agreement-with-Participant-Completion protocol assumes that the participants know when the coordinator has completed all the processing related to a business activity and the Business-Agreement-with-Coordinator-Completion protocol notifies the participants when the coordinator has received all requests.

A participant who has registered the Business-Agreement-with-Participant-Completion protocol

informs its coordinator by sending a Completed notice when it has done its entire works for a business activity. The coordinator should reply with either Close or Compensate message depends on the circumstance. The participant receives a Close instruction if the activity has completed successfully. If it gets a Compensate instruction instead, the coordinator will undo the completed work and will have to restore the data recorded from the initial condition. The participant may encounter a problem or fail during the processing of the activity, in which case, it must signal the coordinator with an error message. If it gets the Fail message, the coordinator will acknowledge the participant by a Failed notification.

Upon receiving a CannotComplete notification, the coordinator learns that the participant cannot successfully finish its work. On sending out this message, the participant discards all its pending work and cancels all related executions, and exits the current business activity. On receiving such a message, the coordinator is required to notify the participant with a NotCompleted message. In the active state, the coordinator could cancel any transaction by using the Cancel notification, and the participant will respond with a Canceled message if it receives the message.

In the Business-Agreement-with-Coordinator-Completion protocol, the completion decision comes from the coordinator. The coordinator sends a Complete message to the participants informing them that they won't receive any new requests within the current business activity and it is time to complete the processing. The participant then replies with a Completed message if it could successfully finish its work

BYZANTINE FAULT TOLERANT WEB COORDINATION

In this section, we first introduce the general Byzantine fault tolerance technique. It is followed by a discussion on how to apply the BFT technique for Web services coordination within minimum

runtime overhead by exploiting the semantics of the Web services coordination.

Byzantine Fault Tolerance

A general purpose BFT replication algorithm is designed for a client-server architecture where the clients issue requests to the replicated server replicas. A Byzantine faulty replica may use behave arbitrarily to prevent the normal operations of a replica. In particular, it might propagate conflicting information to other replicas or components that it interacts with. To tolerate f Byzantine faulty replicas in an asynchronous environment, we need to have at least $3f+1$ number of replicas (Castro & Liskov, 2002). One replica is designated as the primary and the remaining replicas are backups.

The client first sends its request to the primary replica. The primary then broadcasts the request message to the backups and also determines the execution order of the message. To prevent a faulty primary from intentionally delaying a message, the client starts a timer after it sends out a request. It waits for $f+1$ identical replies from different replicas. Because at most f replicas are faulty, at least one reply must come from a correct replica. If the timer expires before it receives a correct reply, the client broadcasts the request to all server replicas. This enables the correct replicas to detect the primary failure so that a new primary can be elected (this is often called a view change).

All correct replicas must agree on the same set of input messages with the same execution order. In other words, the request messages must be delivered to the replicas reliably in the same total order. A BFT replication algorithm, such as PBFT (Castro & Liskov, 2002) is designed to meet this objective.

During the normal operation, the PBFT algorithm uses three phases to commit the total order of a request. During the first phase, often referred to as the pre-prepare phase, the primary multicasts to the backups a pre-prepare message containing the client's request, the current view number, and the sequence number of the request.

A backup verifies the pre-prepare message and control information proposed by the primary for the purpose message ordering and possibly for controlling nondeterministic operations. If the backup accepts the message, it starts the prepare phase (i.e., the second phase) by multicasting to the backups a prepare message containing the ordering information and the digest of the request message being ordered. A replica (including the primary) waits until it has collected matching prepare messages from $2f$ other replicas and the corresponding pre-prepare message. It then starts the commit (i.e., the third phase) by multicasting a commit message to other replicas. The commit phase ends when a replica has received matching commit messages from $2f+1$ replicas (including the one it has sent). At this point, the request message is totally ordered. The message can be delivered to the server application if the replica has delivered all previously ordered requests.

Applying the BFT Techniques Smartly to Web Services Coordination

Because the interactions between the coordinator (replicated) and other components in Web services atomic transactions and business activities must conform to the WS-AtomicTransaction and WS-BusinessActivity standards, there is no reason not to exploit the semantics specified in these standards to significantly reduce the runtime overhead of achieving Byzantine fault tolerance. The specific semantics of the Web services coordination enables us to apply the following optimizations (Chai et al., 2013; Zhang et al., 2012):

Partitioning of the requests. Without the knowledge of application semantics, all requests received at the replicated coordinator would have to be totally ordered and executed sequentially according to that total order. This would severely limit the system throughput and increase the end-to-end latency experienced by clients under heavy load. With the knowledge of the Web ser-

vices coordination context, however, we can see that the requests that belong to different atomic transactions or business activities are handled by different coordinator objects, hence, they can be executed in parallel without causing inconsistency among the replicas.

Using source ordering instead of total ordering for business activities. For business activities, requests within different business activities are handled independently by different coordinator objects. Hence, their relative ordering does not result in conflicting state transitions of the Coordination service. These include all requests for the Registration and Coordinator services, such as the Registration requests. For the Activation requests, even though they are handled by the same object, their relative ordering does not affect how the coordinator objects are created. One concern is the activity context id, which must be unique for each business activity. We modified the implementation such that the coordinator would use a client-supplied unique id to ensure replica consistency. Hence, the requests are commutative with each other even if they belong to the same business activity. Hence, they can be processed in parallel.

Deferred Byzantine agreement. Even for commutative requests, all nonfaulty replicas must deliver the same set of requests to ensure replica consistency. Even though the mechanism to ensure this is lightweight, it would nevertheless incur a performance penalty if the number of commutative requests is large. For a session-oriented application, such as an application uses WS-AtomicTransaction or WS-BusinessActivity, it is possible to defer the Byzantine agreement for the set of commutative requests at the end of the session to reduce the runtime overhead. More specifically, in a Web service atomic transaction, the agreement on the registration requests, which are commutative with each other, are deferred until the transaction commitment time. Furthermore, the Byzantine agreement on the participants set is combined with that for the transaction outcome.

FUTURE TRENDS

The BFT mechanisms described in the previous section are specifically handcrafted for Web services coordination. Although the mechanisms are optimal as a way to enhance the trustworthiness of Web services coordination, they cannot be directly applied to other distributed systems. We see two future trends with respect to developing techniques to enhance Web services and distributed applications in general: (1) automating the application semantics discovery; and (2) reconstructing applications using commutative data structures or software transactional memory.

We have been exploring methods to automate the discovery of application semantics, including the dependency analysis of interface specifications, such as that written by the Business Process Execution Language (Fu et al., 2004; Ouyang et al., 2007) for business transactions, source code static analysis, and modeling and pattern recognition of messages exchanges. We have documented a number of interaction patterns as the foundation for automated analysis of application semantics for Byzantine fault tolerance (Chai and Zhao, 2012).

An alternative approach to implementing highly efficient solution for Byzantine fault tolerance is by using commutative data types (Shapiro et al., 2011; Prego et al., 2009). Because all operations on the replicas are commutative, the need for carrying out Byzantine agreement is minimized. We have designed a system that requires only periodic synchronization of operations (Chai and Zhao, 2014). Similarly, the server application can be constructed using software transactional memory (Shavit & Touitou, 1997), which enables automatic analysis for possible concurrent processing of requests without application semantics (Zhang and Zhao, 2012). The biggest benefit for this approach is that the solution is ignorant to application semantics, which means any solution designed will be readily applicable to other applications written using commutative data types. The down side of this approach is that the applications would have to be redesigned and implemented using commutative data types.

CONCLUSION

In this article, we introduced Web services coordination and its applications to Web services atomic transactions and business activities, and presented a overview of our recent works on enhancing the trustworthiness of Web services coordination for business activities and transactions. We argue that even though it is possible to use a general purpose BFT replication algorithm for Byzantine fault tolerant replication of a Web services coordination service, doing so naively would incur unacceptable runtime overhead. Instead, by exploiting the application semantics, much lighter weight mechanisms can be designed to enhance intrusion tolerance, and hence the trustworthiness of systems that require Web services coordination.

KEY TERMS AND DEFINITIONS

Atomic Transaction: An atomic transaction in the context of Web services refers to a distributed transaction to be executed atomically. It should exhibit the atomicity, consistency, isolation and durability properties, just like a local transaction.

Business Activity: A business activity is usually long running and requires flexible outcomes. A Web service business activity must conform to the

WS-BusinessActivity specification and adopts one of two two coordination types, Atomic-Outcome and Mixed-Outcome, and one of two coordination protocols, Business-Agreement-with-Participant-Completion and Business-Agreement-with-Coordinator-Completion. Either protocol can be used with either coordination type.

Business Process Execution Language (BPEL): It is a computer language used to describe the actions and execution order of these actions within a business process. It is designed specifically for the Web services paradigm. A BPEL for Web services was standardized by OASIS.

Byzantine Fault Tolerance: A replication-based technique used to ensure high availability of an application subject to Byzantine fault.

Byzantine Fault: It is used to model arbitrary fault. A Byzantine faulty process might send conflicting information to other processes to prevent them from reaching an agreement.

Distributed System: A distributed system is a computer network system, shown to end users as a single machine but actually work with a set of independent computers connected.

Replica Consistency: The states of the replicas of an application should remain to be identical at the end of the processing of each request. Replica consistency is necessary to mask a fault in some replicas.

Web Services: The Web services technology refers to the set of standards that enable automated machine-to-machine interactions over the Web. The core standards include XML, HTTP, SOAP, WSDL and UDDI.

Usability of CAPTCHA in Online Communities and Its Link to User Satisfaction

Samar I. Swaid

Philander Smith College, USA

INTRODUCTION

CAPTCHA- Completely Automatic Public Turing test to Tell Computers and Humans Apart- is a security application that is used by many websites to avoid spamming and hacking. CAPTCHA provides a test that humans are able to solve, but computer programs cannot, to defeat websites and stop spammers and hackers. CAPTCHA test can be viewed as a function of random input that generates a challenge test and a solution. Previous research found that website users spend on average 10 seconds per CAPTCHA (Sutherland, 2012), which suggests for 200 million CAPTCHA that are solved by human users every day, more than 5000,000 hours on daily basis are lost productivity (Sutherland, 2012). CAPTCHA is developed as an instrument to limit misuse of websites that offer free services of email creation, weblogs posting, social networking, online voting, online games online banking, or chat rooms, etc. With this aim in mind, several CAPTCHAs (Boshmaf et al., 2012; Coats and Baird, 2001; Chellapilla and Simard, 2005a; Von Ahn and Blum, 2005) are developed. CAPTCHAs share a number of common characteristics: (i) automated test; (ii) publicly available; (iii) separability of test- generation and solution; and (iv) defeating attacks (Fidas et al., 2011, Swaid, 2013). A number of different techniques for generating CAPTCHAs have been developed, each satisfying the criteria of CAPTCHA test described above.

CAPTCHA types can be categorized to five main types: (i) text CAPTCHA such as reCAPTCHA and Gimby CAPTCHA (ReCaptcha, 2015);

DOI: 10.4018/978-1-5225-2255-3.ch702

(ii) image-based CAPTCHA such as ASIRRA (Elson et al., 2007), Bongo (Bongo, 2015) and Pix (Pix, 2015) that rely on image-recognition techniques (Vikram et al., 2011); (iii) animation-based CAPTCHA; (iv) audio CAPTCHA (e.g., ReCaptcha Audio Captcha, Digg, and (v) other (e.g., mathematical functions, games, multiple choice, and cognitive based CAPTCHA) (Hernandez-Castro and Ribagorda, 2010; Yamamoto et al., 2010). Text CAPTCHA is the most common type where the user is presented with a challenge-response test in a form of numbers and letters, and user needs to strike in the right characters in the given text box. In this chapter, the author uses text CAPTCHA and CAPTCHA alternatively focusing on usability of text-based CAPTCHA that is formed of randomly generated sequence of letters and/or numbers that appear as a distorted image.

Cracking CAPTCHAs

Cracking CAPTCHA and bypassing the CAPTCHA tests have attracted a number of studies to examine methodologies used in solving CAPTCHA. Generally, text CAPTCHA cracking needs three steps. First phase is pre-processing CAPTCHA by removing background, color and added noise. Second, a segmentation process is used to locate individual character in CAPTCHA challenge. Finally, a classification or recognition phase is applied to solve CAPTCHA, such as using standard OCR software (Serrao, et al., 2013; Sutherland, 2012), CAPTCHA farms (Serrao, et al., 2013), or CAPTCHA smuggling (Egele et al., 2010). In addition, there are other alternatives of

commercial software that are developed to crack CAPTCHA such as Death BY CAPTCHA, CAPTCHA Sniper, Automated CAPTCHA Bypass, CAPTCHA Monster or PWNTCHA (Serro et al., 2013). Exploring mechanisms to crack CAPTCHA and its relation to usability is also important and of practical relevance, but beyond the scope of this chapter.

CAPTCHA Usability and Online Communities

In general, we may define the concept of usability as the effort required to use a computer system. For instance, Nielsen (2003) suggests that usability concerns several aspects such as the ease with which the user is capable of learning to manage the system, the ease of memorizing the basic functions, the grade of efficiency with which the site has been designed, the degree of error avoidance and the general satisfaction of the user in terms of manageability. Therefore, greater levels of usability will be associated to lower levels of difficulty to manage that functionality (Davis, 1993) and, as a result, usability is traditionally considered a key factor for predicting intentions to use a system (e.g. Davis, 1993). More specifically, text CAPTCHA usability might reflect perceived ease of solving CAPTCHA test (Swaid, 2013) explaining satisfaction. Designing successful CAPTCHA that is unsolvable by CAPTCHA solving software, yet, a user friendly one, is a challenging task (Ahmad and Yan, 2010). Several proprieties to make CAPTCHA resistant to Optical Character Recognition (OCR) software can make CAPTCHA unusable

(Sutherland, 2012) and therefore, suggest users' dissatisfaction.

Today, millions of people join online social gathering spheres to chat, to debate, to play games, to ask for information, or to find social support (Preece, J. and Maloney-Krichmar, 2003). Some forms of such online gatherings come in the form of forums, discussion groups, and social networking sites among others. These online social gatherings are known by a variety of names including 'online community', that is described as 'cultural aggregations that emerge when enough people bump into each other often enough in cyberspace' (Rheingold, 1994, p. 57). To eliminate automated spammers and other computer agents who are attempting to violate community norms, online communities ask applicants to complete a CAPTCHA test before subscribing. Studies showed that new comers to online communities are unable to join due to the entry barrier posed by visual CAPTCHAs (Chandrasheka, 2010).

A CAPTCHA that is robust, yet, unsolvable by humans is useless. The issue of usability has been studied focusing on the functional level (Ahmad and Yan, 2010; Burstein et al., 2010), however, the ultimate effect of CAPTCHA usability on legitimate goal-oriented users is not well documented in literature (Motoyama et al. 2010). According to Ellson et al. (2007), even relatively simple challenge can drive away a substantial number of potential customers to websites. Thus, a methodological analysis is needed for CAPTCHA schemes used in websites for online communities to understand the correlations between design characteristics and users satisfaction.

Figure 1.

Background

Over the past decade, a number of CAPTCHAs have been created to differentiate humans from computer programs. Unsurprisingly, CAPTCHAs have been evaluated in terms of its robustness (Azad and Jain, 2013; Chew and Baird, 2003; Chellapilla et al., 2005a, 2005b), its economic context (Motoyama et al., 2010), but limited number of studies focused on usability issues of text CAPTCHA. One study by Ahmad and Yan (2008) analyzed CAPTCHA technically to find attributes of content, presentation and distortion to explain usability. In another study by the same authors they shed light on the role of color on CAPTCHA

usability (Ahmad and Yan, 2010) (see Table 1). A study by Sutherland (2012) focused on analyzing different properties of layout CAPTCHA in terms of background color and integration with the website. In an attempt to maximize the usability of CAPTCHA, security features of visual, anti-segmentation and anti-recognition were identified and applied to create two new CAPTCHA schemes for Google (Bursztein et al., 2014; 2011). In the work of Swaid (2013), a think-a-loud protocol and a sorting task are conducted to understand the dimensionality of CAPTCHA usability. The study applied a formative approach in operationalizing the latent construct of usability (see Table 1).

Table 1.

Reference	Focus/Research	Usability Issues in CAPTCHA Design
Yan and El-Ahamad (2008)	Text-CAPTCHA/Content Analysis and	-Distortion (distortion method and level, confusing characters) -Content (Character set, string length, predictability, randomness of letters, , offensiveness of words) -Presentation (front type, and size, image size, use of color, integration with web pages.
Ahmad and Yan (2010)	Text-CAPTCHA color use/Content analysis and Experiment	Complicated background color effects negatively both security and usability Using few colors (e.g., two colors) is recommended for both usability and security of CAPTCHA
Bursztein (2011)	Text-based Captcha/ content analysis and experimentation	Anti-Recognition -Use of Multi font: Use of multiple font-face - Use of character-set: Character-set scheme used -Use of font size: Using variable font size -Use of Distortion: attractor fields - Use of blurring: Use of blurring letters - use of tilting: rotating characters with various angles - use of waving: Rotating characters in a wavy fashion Anti-Segmentation -Complex background: try to hide text in complex background -Lines: adding lines to prevent solver from knowing the real character segments - Collapsing: Remove Space between characters to prevent segmentation
Sutherland (2012)	Text CAPTCHA/content analysis of several CAPTCHA	Character set size(size of character set, types of characters; lower and upper case characters; String length(number of characters, dictionary word; fixed length vs. variable length scheme);distortion (variety of fonts styles, complex background, stray lines types, collapsing)
Swaid (2013)	Text-CAPTCHA/Think-Al-Loud Protocol and Card-Sorting task	Content :Extent contents embedded in CAPTCHA is understandable Format: Extent CAPTCHA content is formatted and presented to users Distortion: Extent distortion is applied to CAPTCHA's text; Services: Extent CAPTCHA provides services to facilitate solving CAPTCHA
Burztein et al.,(2014)	Text CAPTCHA/ Content analysis and experiment	-Visual: character set, character count, font size, font families, foreground color, background color, -Character overlap, random dot size, random dot count, line types, lines count, line positions, similar foreground/background colors - Rotated character count, rotated character degrees, vertical shifting sizes, character size variations, character distortion

CAPTCHA USABILITY: THE STUDY

To understand the relationships among dimensions of CAPTCHA usability and behavioral variables of user satisfactions, the study is designed as two-phase one. First phase would focus on surveying the top 50 most popular online communities' websites to identify CAPTCHA use; while second phase would collect users' perceptions on CAPTCHA usability and their satisfaction with the registration process.

CAPTCHAs in Top 50 Online Communities: A Content Analysis Approach

To gather exiting text CAPTCHAs exit in top 50, most visited online communities websites, the author uses Alexa (Alexa.com, 2015), a web tracking and statistics gathering service, to determinate the top 50 most popular websites for online communities visited as of February 2015. Of the top 50 online communities, the ones that follow the criteria below are selected:

1. Website is one of the online communities' platforms.
2. Website offers registration, blogging, or somehow updating activity.
3. No membership fee is required.
4. English-speaking website.
5. Challenge users with static text CAPTCHA. Text CAPTCHAs with animation or other types of CAPTCHAs (e.g., CAPTCHA used by Yahoo) are excluded from the study.

Applying the criteria listed above, the author confirmed findings of previous study on CAPTCHA usability using qualitative approach (Swaide, 2013). Analysis revealed that there are four main text CAPTCHAs used by the most popular online communities websites (see Table 2). Unsurprisingly, ReCAPTCHA was the dominant CAPTCHA used by most of the online communities, while SolevMedai CAPTCHA and Mollom were realized in less number of online communities. This is in line with other market analysis reports that found ReCAPTCHA market share is about 99% (WebAnalyzer, 2016). Some of the CAPTCHAs were excluded for reasons of animation added, non-text interactive CAPTCHA or image orientation CAPTCHA (see Figure 2). These mainly were found at Yahoo.com, Namepros.com and Care2.com. Next, a content analysis to CAPTCHA is applied, as follows.

Content analysis as a technique is used to examine artifacts of social communications that might come in the form of written documents, multimedia content and any form of transcriptions of recorded verbal. As Holsti noted, content analysis is "any technique for making inferences by systematically and objectively identifying special characteristics of messages". Based on this definition, content analysis can be applied on messages that come in form of written text, photographs, and/or multimedia content, to identify specific characteristics of the message. Similarly, Krippendorff defined content analysis as a research technique for making valid and reliable inferences from data to their context (Krippendorff, 2013). Weber (1990) defined content analysis as research methodology that utilizes a set of procedures to

Figure 2.

make valid inferences from text. Content analysis is most conveniently used with textual types of data such as online comments, online content, blogs, and open-ended survey questions (Krippendorff, 2013).

Dimensions of CAPTCHA Usability

Text CAPTCHA found in online communities exhibits four main dimensions that can be used to measure the usability of CAPTCHA. Based on previous research (i.e., Al-Ahmad and Yah, 2010, Burztein et al., 2014; Swaid, 2013), it is suggested that usability of CAPTCHA is a function of four dimensions: Content, Visual Layout, Distortion and Service. To understand the relationships among dimensions of CAPTCHA usability and perceived usability and satisfaction with the registration process, dimensions of CAPTCHA usability are developed as reflective latent constructs represented by at least three measures (Hatcher,

1994) (see Table 3). The conceptual model of the study also examines the effect of perceived usability on satisfaction (see Figure 3).

Following the recommendation of Churchill (1979), this study adopts the following steps: (i) latent constructs are conceptualized by defining the domain of the constructs; (ii) dimensions are operationalized focusing on the content validity of the dimensions, (iii) data are collected using the developed scale, (iv) reliability analysis and factor analysis are applied to assess the reliability and validity of the developed model. Endogens variable of overall CAPTCHA usability is adopted from the System Usability Scale (SUS) modified by Lewis and Sauro (2009). Satisfaction with registration process of website is adopted from Flavia et al. (2006). Confirmatory factor analysis (CFA) and Structural Equation Modeling (SEM) are conducted to examine the reliability and validity of the measurement model and to test associations hypothesized in research model.

Figure 3.

RESULTS

The 13-Item battery of CAPTCHA usability is arranged in a survey instrument to be measured using a seven-point Likert scale ranging from (1) strongly disagree to (7) strongly agree. In addition, a 5-item construct representing usability and 3-item construct representing satisfaction are embedded in the survey. Total of 124 college students have been invited to take part in the study for a credit in one of the universities in the Mid-South of the United States. About 60% of the participants are females, whom ages range from 19 to 35 years old. All participants have some type of participation in online communities such as forums, discussion groups, and social networking websites (see Figure 4).

The participants are first presented with questionnaire asking their experience with web browsing, experience with CAPTCHA, and level of engagement in online communities. Then, participants are asked to solve survey questions after they are challenged with three CAPTCHAs to solve.

Measurement Model

The measurement model is assessed by CFA to confirm the dimensionality of CAPTCHA usability. Chi-Square value is 2.18 less than the three recommended value by Bagoozi and Yi (1988). Other fit indexes show good fit for the measurement model. The GFI is 0.92, greater than the cut-off value of 0.90 recommended (Hatcher,

Figure 4.

1994). The adjusted goodness of fit (AGFI) is 0.90 (Bagozzi and Yi, 1988). The root mean square error of approximation (RMSEA) is 0.049, which also suggests a good fit with data collected. Reliability was assessed using Cronbach's alpha which ranges from 0.711 to 0.889, exceeding the 0.70 threshold, recommended by Nunnally and Bernstein (1994) (see Table 3). As factor loadings exceed 0.70, this indicates acceptable item convergence on its intended constructs, indicating validity (Bagozzi and Yi, 1988).

Structural Model

Hypotheses of research model are tested using the structural equation modeling. Overall fit statistics suggest that the model has adequate model fit (GFI = 0.91; AGFI = 0.90; CFI = 0.91; RMSEA = 0.043). The model fit indexes all exceeded their respective acceptance levels, indicating that the structural model fits the data well. In order to test research hypotheses, structural coefficients for model paths are calculated (see Table 4).

Discussion

This study examined the dimensionality of text CAPTCHA usability and examined how CAPTCHA usability dimensions affect perception of CAPTCHA usability users' satisfaction with

registration process. The analytical results of this study are discussed below.

First, the analytical results shows that CAPTCHA usability can be explained by CAPTCHA content, visual layout, distortion and service. Usability is most strongly affected by visual layout. Online communities thus need to ensure that visual layout introduced by CAPTCHA text is appropriate and solvable to users. Second, the dimension of content significantly affects CAPTCHA usability perception. This finding might be explained by the fact that users expect CAPTCHA with content from character set and symbols they are familiar with. Third, the distortion dimension is a significant predictor of text CAPTCHA usability. Other studies that analyzed the CAPTCHA suggest that distortion might affect the perception of CAPTCHA usability. Therefore, to enhance users satisfaction with the registration process, online communities should use CAPTCHA that applies distortion technique in a way that would not affect CAPTCHA usability of CAPTCHA, and still can be used to stop spam.

Next, although service dimension had only a mild effect on CAPTCHA usability perception in this study, its importance should not be underestimated. Managers of online communities should pay careful attention to this aspect. Particularly, CAPTCHA should be designed with features that facilitate its solvability such as explaining reasons

Table 3.

Measures	Mean	Std	Factor	Construct Cronbach's Alpha
Content: C1- CAPTCHA Text is of appropriate content C2- CAPTCHA Text is something I expected C3- I feel comfortable with CAPTCHA content	4.88 4.55 4.23	0.80 0.91 0.88	0.808 0.767 0.751	0.889
Visual Layout: V1- CAPTCHA text is of appropriate visual look V2- CAPTCHA text is presented in a way that I can understand V3- CAPTCHA text is of appropriate color V4- CAPTCHA text is of appropriate design	4.44 4.34 4.01 4.09	0.78 0.89 1.01 0.78	0.883 0.834 0.821 0.818	0.878
Distortion: D1- Text CAPTCHA is distorted with appropriate level of noise D2- Text CAPTCHA is distorted with appropriate type of noise D3- Text CAPTCHA is manipulated in a way that does not make it difficult to solve it	4.80 4.56 4.03	0.80 0.77 0.86	0.854 0.834 0.831	0.823
Service: S1- CAPTCHA test provides help to solve CAPTCHA test S3- CAPTCHA test provides functions to bypass CAPTCHA test	3.89 4.33	1.22 0.98	0.721 0.801	0.711
Overall CAPTCHA Usability CU1: I think that I would like to use this CAPTCHA system again CU2: I thought the system was easy to use. CU3: I found the various functions in this system were well integrated CU4: I would imagine that most people would learn to use this CAPTCHA system very quickly CU5: I felt very confident using the system.	4.23 4.11 3.89 4.30 4.09	1.01 1.23 .099 1.14 1.15	0.891 0.867 0.877 0.801 0.859	0.801
Satisfaction with Website: SAT1: I think that I made the correct decision to use this website SAT2 The experience that I have had with this website during registration has been satisfactory SAT3: In general terms, I am satisfied with the way that this website has carried out registration process	3.99 4.33 4.29	0.89 1.12 1.09	0.800 0.779 0.780	0.811

behind using CAPTCHA and providing users with the ability to switch to other non-text CAPTCHA (e.g., audio CAPTCHA) to enhance accessibility (Kuzma et al., 2011). Additionally, this study found a positive relationship among CAPTCHA usability and satisfaction with registration when using online communities.

IMPLICATIONS AND FUTURE RESEARCH DIRECTIONS

This study has the following implications for practitioners initiating or currently using CAPTCHA in their online communities. First, this study suggests that to enhance users' satisfaction, online communities should employ CAPTCHAs that are carefully tested in terms of its usability, addressing each of CAPTCHA dimensions of content, visual layout, distortion and service. Practitioners are advised to use the scale to measure each dimension while testing the appropriate mix of features in an iterative fashion to identify aggressive distortion, unnecessary characters or inefficient collapsing to exclude from CAPTCHA test. The scale might be used as a starting point to understand the non-linear effect of interactions (Bursztein et al., 2014) on CAPTCHA's usability. Secondly, there are variety of commercial CAPTCHA. Managers are advised to use CAPTCHAs after careful testing. Thirdly, practitioners are advised to employ CAPTCHAs that offer features enhancing accessibility such as switching to audio CAPTCHA for users with vision problems or contacting a technical person to help in bypassing CAPTCHA test. Such services would improve the perception of responsiveness in web-based service-oriented systems (Swaid and Wigand, 2009) such as online communities.

Although the study develops a scale following a systematic approach and validity testing, limitations need to be addressed. First, participants in this study are college students. Although online communities' population resembles the college students, replicating the study with non-college students might suggest additional findings. Sec-

ond, in this study, the author focused on perception of usability and satisfaction as behavioral variables. Future research can test relationships between CAPTCHA usability and other variables such as intentions to recommend and loyalty to online communities. Third, the growth of the internet and online communities will continue, and future research can replicate the study solely involving objective measures to assess solvability and usability of CAPTCHA such as time consumed and number of errors while solving CAPTCHA test. Forth, evidence exists that the relative importance and possible meaning of CAPTCHA usability may differ across cultures (Zhu and Keough, 2014). Thus, the study can be replicated to provide cross-cultural comparisons. Similarly, considering the cognitive characteristics of individuals, their learning styles (Belk et al., 2013, Germanakos et al. 2009; Grafs et al., 2005) or demographic variables (Bursztein et al., 2010) might point out other fruitful findings in terms of how to improve usability. Finally, as smartphones are widely used to access web services offered by online communities, it is worthy to address usability issues of text CAPTCHAs on smart phones.

This chapter is intended to provide an essential step in quantifying usability of text CAPTCHA contributing to the limited knowledge in this area. There is more work to be done to understand CAPTCHA usability considering a number of socio-technical and cultural challenges that relates to CAPTCHA engineering.

CONCLUSION

The conclusions drawn from this study make contributions in two main areas. First, this study is the first one to develop an dimension-based instrument to measure text CAPTCHA usability applying the reflective approach in dimension construction. Second, this study identified text CAPTCHA usability dimensions that affect CAPTCHA usability perception, which in turn is significantly related to users' satisfaction. This chapter is intended to

provide an essential step in quantifying usability of text CAPTCHA contributing to the limited knowledge in this area. Clearly, there is much more work to be done to understand CAPTCHA usability considering the multiple aspects of its dimensions that would support creating not only robust CAPTCHAs but also usable and effective ones. This, however, boils down to solving a number of socio-technical challenges that relate to CAPTCHA engineering.

KEY TERMS AND DEFINITIONS

CAPTCHA: An acronym for “Completely Automated Public Turing test to tell Computers and Humans Apart”. CAPTCHA is a program that protects websites against bots and hackers by

generating and grading tests that humans can pass but current computer programs cannot.

CAPTCHA Usability: Ease of use CAPTCHA scheme and solve its test.

Equation Modeling: Structural equation modeling refers to a set of mathematical models, algorithms, and statistical methods that fit networks of constructs to data. SEM includes confirmatory factor analysis, path analysis, partial least squares path analysis, and latent growth modeling, among others.

Factor Analysis: Factor analysis is a statistical method for data reduction that describes variability among observed, correlated variables in terms of a potentially lower number of unobserved variables called factors.

Online Community: A virtual network of people who communicate with one another through interactive tools such as forums, discussion groups of social networking sites.

User Satisfaction: The attitude of a user to the CAPTCHA Scheme adopted by the website.

Visual Identity Design for Responsive Web

Sunghyun Ryoo Kang

Iowa State University, USA

Debra Satterfield

California State University – Long Beach, USA

INTRODUCTION

Because the web has moved beyond desktop environments, responsive web design requires reconsideration with regard to the interface design and development workflow (Carver, 2015). It is hard to create the same feeling and look across all devices (Moss, 2015), and maintaining a strong, consistent visual identity in a responsive web design is challenging because of this flexible or liquid layout and navigation. This flexible and dynamic design system is known as responsive web design (Marcotte, 2011). Responsive web design has changed the web eco system. Therefore, fundamental changes in web design are necessary to accommodate this variety in interfaces and platforms.

The first impression of a website is affected by the visual design elements of color, typography, and graphic elements (Park, 2016). If the visual design does not immediately connect with a user the likelihood that they will stay on the site is greatly diminished. Therefore, the website must capitalize on a familiar and trusted brand identity or the site must quickly establish a visual identity that is professional and immediately establishes a sense of trust or familiarity in the user (Kang and Satterfield, 2010).

The purpose of this chapter is to identify design strategies for establishing and managing the visual identity of a responsive web design. This chapter revisits the article, *Design Elements and Principles for Maintaining Visual Identity on*

Websites (Kang and Satterfield, 2010), to reflect the changed Web environments with flexible and dynamic web technologies.

BACKGROUND

Responsive Web Design

To create a successful responsive web design, a layout that can easily be customized for different screen sizes is key (Voutilainen, Salonen, and Mikkonen, 2015). According to Voutilainen, Salonen, and Mikkonen, it is important to consider “proportion-based grids and flexible images, where element sizing takes place using relative units instead of absolute ones, and CSS3 media queries, where different styles can be used for different devices (2015).” Since the web page layout is liquid and flexible, the exact structure of the layout would not be an element that can be used to maintain the web site identity. Using images and design elements that can be modified using CSS media queries and script language while still maintaining the essence of the visual characteristics of the site are essential to a successful responsive web design.

Visual Identity Design

According to Perry and Wisnom, the role of visual identity is to translate a company’s brand positioning and verbal identity into a visible vi-

sual representation (Perry and Wisnom III, 2003, p14). Perry and Winsnom outlined the purpose of visual identity as fourfold: “to bring the brand to life by giving character and personality to the positioning and name,” “to enhance brand recognition and recall,” “to differentiate the brand from competition”, and “to tie all the disparate brand elements together with the same look and feel” (Perry and Wisnom III, 2003, pp95-96).

The visual elements such as logos and colors in the identity system can create an immediate sense of recognition for the company, express its character, and build familiarity and trust (Haig and Haper, 1977, p14). According to Kang and Satterfield (2010), “an identity system can be thought of as a tool that is used to maintain a company’s corporate visual image. This system must be flexible enough for different applications, at the same time, tight enough to maintain visual consistency across media.” The most recognizable elements of corporate visual images are the brand logo, corporate colors and the visual identity (or corporate philosophy) as represented through photos, images and other familiar graphic symbols associated with that brand.

A logo or corporate symbol is the predominant visual cue for a business and it conveys the company’s philosophy and message. The roles of corporate symbols are to create awareness; to trigger recognition of an organization; and to activate a stored image of the organization (Dowling, 2001, p 167). Logos are used as a powerful tool for marketing. Customers often make buying decisions based on the brand recognition rather than on the specific characteristics of the product itself. Apple, Google, Coca-Cola, and McDonald’s logos are examples of these types of familiar and trusted corporate symbols.

Color is another important element in the identity system. Examples of color associations are Coca-Cola red, Kodak yellow, and Barbie pink. Thus, color is an important element in any identity system. According to Dowling (2001), color is easier to read than form or shape and it holds the viewer’s attention longer. Color also has

cultural and psychological associations. Therefore, the same color can be interpreted in different ways depending on the culture and context of the situation.

THE VISUAL ELEMENTS OF RESPONSIVE WEBSITE IDENTITY

Maintaining website identity for a responsive web design can be challenging and requires different design strategies from those used for print or traditional desktop web design. The use of logos, icons, symbols, colors, images, and typography for responsive web design need to maintain the visual identity of a site across a variety of sizes and screen configurations.

Use of Web Site Identifier

A site identifier such as the company name, logo, or sometimes both, and a web address (URL) is a unique feature identifying a website and the role is more important in the responsive web design. These site identifiers mainly logos are generally located in the top left corner with fixed location no matter in the flexible or dynamic layouts. Making the brand easy to see and identify is critical in insuring that a user will quickly identify the site and associate it with other sites on other devices and platforms.

According to Steve Douglas (2015), 93% of logos from the top 100 brands are simple enough to recognize at small size. For example, Apple and Nike’s logo is very simple but yet unique. It can be recognized with very small size even without the company name. In 2005, Google changed its typeface from serif to sanserif. One of reason for this change is for “scalable mark that could convey the feeling of the full logotype in constrained spaces (<https://design.google.com/articles/evolving-the-google-identity/>).”

Therefore, a logo as a site identifier should have a unique appearance to identify the characteristics of a particular web site, easier to recognize and recall, and scalable for different devices.

Use of Color

Color becomes the more powerful tool to build web site identity in the responsive web design. Color can be displayed slightly different in each device but it is much easier keeping the same color on the screen compared to print. According to the top 100 brand in 2016 from Forbes (<http://www.forbes.com/powerful-brands/list/>), blue and red are still the most popular color for cooperate logos. However, Nike uses a black logo and recently their web site (http://www.nike.com/us/en_us/) used this black and a monochromatic color scheme to integrate their responsive web site designs. The black and monochromatic color scheme enhanced the memorability and made Nike stand out among the numerous more colorful web sites. This emphasizes that the fact that the use of color as “a ubiquitous perceptual experience” (Elliot and Maier, 2007, p250) can be used in unique or distinctive ways to attract a viewer’s attention.

Use of Image

Graphics and images can be used as visual cues to forecast the characteristics of a website. According to Donald Norman (2004), photography has a strong appeal to human emotions (p50) and photographic images can be used to strengthen the visual appearance of an interface. For example, photographs showing families give a feeling of comfort, security, and trustworthiness and are perceived to be more friendly than photos that feature single men, single women, or couples (Ha and Kang, 2010). Another study (Park, 2016) showed that web users found websites that included photographic images were perceived to be more attractive than websites without photographic images. Thus, photos, graphics, illustrations, or icons can enhance the visual appearance of an interface and give users a more positive impression of the site. In the responsive web design, images must be scalable and set with a percentage, not as a fixed width. This allows images fit into the grid and allows the images to resize without sacrificing any of their aspect ratios.

Use of Layout

The layout of an interface is a visible form of its information architecture. Most web pages are divided into four main areas: site identifier; navigation; content; and footer (Kang & Lee, 2003) and these four areas have not changed in responsive web environments.

According to Kang and Satterfield (2010), “the layout is designed based on the quantity of content information, numbers of organizational categories, and marketing and design strategies.” However, in responsive web design, the layout is flexible and dynamic based on the screen size. Therefore, before a designer begins coding the web site, a layout style should be carefully considered to create an appropriate and consistent visual appearance across all screen configurations and platforms. Figure 1 shows how the layout and design elements translate between the horizontal desktop web screen and the smaller vertical smartphone screen.

Use of Design System

The four main areas of a web; site identifier; navigation; content; and footer need to be organized in a system to maintain web site identity across various screen formats and sizes. The navigation bar plays an important role in maintaining visual consistency across multiple devices. Accordingly, design style is also an important element in responsive web design. A consistent visual style gives users a unified feeling between formats. A unified look and feel across the various platforms can also easily create a strong web site identity.

The design system should be flexible enough to be applied dynamically to a variety of devices yet strict enough in its use of a design system to maintain visual consistency. It is also important to consider the limitations and variability of web sites. For example, CSS 3 and media queries make it possible to control the web page layout.

A grid is a good way to improve usability and give a consistent look and feel to the page (Watzman 2003, pp268-285). However, in re-

Figure 1. Desktop Web Screen and Smart Phone Screen

sponsive web design the number of columns in a grid differs between devices and design elements will dynamically move around the web page. In order to compensate for these differences in layout, the use of color, typeface, and design style will be important in maintaining a consistent visual identity. A very tight systematic approach and design strategies are required to maintain an effective visual identity across all platforms in responsive web design.

Strategies for an Effective Responsive Web Site Identity Design

The basic strategies required to maintain a strong visual identity in web design remain the same. As Kang and Satterfield (2010) note, “the most important consideration in the creation of web site identity is an understanding of a company’s goals for having the web site and the users’ goals for visiting the web site. The design strategy for a web site comes from an understanding of the business and how to provide appropriate information in this media. It is also determined by the

target audience and an understanding of the web’s limitations and strengths.”

An effective identity design will use visual identifiers such as logos, icons, symbols, colors, images, and typography to maintain the brand identity of a responsive site across a variety of sizes and screen configurations. It will also capitalize on a user’s familiarity and trust in the brand’s identity. In order for the site to gain this advantage it must quickly align itself with its brand through the use of these visual identifiers and through the cohesive use of the four main areas of organization of a responsive web; the site identifier; navigation bar; site content; and the footer. For responsive web design the following are needed for each of these design and organizational elements.

Interaction and User Experience

The best web site identity combines effective usability and user experience. As Norman mentioned (2004), “attractive things make people feel good (p19)” and create positive emotions. Thus, a combination of good usability and providing

positive experience is essential with the appropriate web site identity elements. “Appropriate visual elements such as logos, images, colors, and typography will create a positive user experiences and build good brand impressions. Understanding the balance between usability and user experience will help designers create successful web site identity systems.” Therefore, usability and user experience are vital to building a successful responsive web site. “In a broad sense, usability can be considered a part of user experience. User experience depends on visual elements, which in turn affect the final appearance of web site design (Kang and Satterfield, 2010). Designing appropriate interactions for a responsive web site is essential to successful usability. Each device requires different interactions. For example, typing on the keyboard of a laptop or desktop computer is a very different experience from typing on a touch screen. According to Kang and Satterfield (2010), “to build a successful web site identity, a designer must understand not only web site usability but also users’ emotions and experiences. Users will experience a web site through navigational interfaces. An interface is a communication tool between the web site and the users. The interaction that takes place as facilitated by the interface is a personalized experience for each individual. Symbols, icons, colors, text, and images are the tools that create this user experience. When a web site has unique icons for navigation, people will remember the icons and identify the web site through them.”

Visual Identifiers and Branding

- **Logos or Branding:** Brand symbols and logos must be used consistently and must scale to fit the screen in the site identifier area of the screen.
- **Icons and Symbols:** The use of screen icons should remain consistent and the icons should be easily visible and readable in a variety of sizes. The use of complicat-

ed symbols or low contrast colors should be avoided to maintain a consistent look and an effective readability in all sizes.

- **Color:** Color should be selected for best readability in content areas and to create brand recognition. Colors should be used to create emphasis or visual hierarchy in similar ways in a variety of screen formats. Text, icons and symbols should use colors that are highly visible and readable in small sizes on small devices and not overpowering in larger screens.
- **Typography:** Type should be in colors that maintain readability in a variety of sizes. The typefaces used should have a variety of weights and styles to support readability and visual hierarchy in various sizes. Color should be used to maintain and reinforce the visual hierarchy of the type such as using darker colors for body copy and lighter colors for headings and subheads. Brand colors may be used to create brand identity or for emphasis.

Web Site Organization Elements

- **Site Identifier:** A site identification area must be clearly established through the use consistent use of brand symbols and logos. It should have the top level of visual hierarchy on the screen and the users should be able to quickly associate this web site with its brand affiliation.
- **Navigation Bar:** The navigation bar should quickly and easily orient the user to the site’s structure or information architecture. The location and visual style should be easy to find and readable across all devices even though the location and screen orientation may vary. The navigation system should be clear and consistent in its use of verbal language, symbols and categories of information. The number of categories should be visually compatible with

the amount of space available on a variety of devices and consistent with how the user interprets the information in each category.

- **Site Content:** Site content should be designed and written to be easily accessible at a variety of sizes and scales. Writing should be concise and use headings to help users orient themselves in the content and have a clear expectation of what they are reading or seeing. Content should be developed to be accessed with the fewest barriers such as excessive click throughs or long scrolling pages.

Visual hierarchy should be reinforced by selecting a clean, bold font for headings and an easily readable font for content areas and descriptions. The visual hierarchy can be further reinforced by adding color to major headings and using moderate to high contrast between the body copy and the background. Symbols and icons can be added to link text areas to the navigation categories or to create a visual contrast that will draw attention to key information in the body copy and help user's better understand the content or more quickly find an element of text.

Photography and illustration can be used in the content area to establish a sense of connection with the user by enhancing the relatability of the content to their lifestyle or to clarify the verbal content of a site such as including a construction diagram along side a list of instructions. A robust and sensitive combination of visual and verbal information can greatly enhance the perceived value and visual appeal of a responsive web site and should be used to create a strong connection with a company's corporate branding and philosophy.

- **Footer:** The footer should be consistently located at the bottom of the screen or device. It should include information that will allow the user to solve problems or access the company in appropriate ways. The footer should be clearly identified and separate from the content area. Color and

icons or symbols may be used to distinguish the area visually and to identify key associations with other organizations.

CONCLUSION

Responsive web design involves teamwork in various areas and it is critical that each individual who involved in the process must understand the roles of usability and user experience in order to build a successful responsive web site identity. For the responsive web, a lean UX (Gothelf and Seiden, 2013) method is recommended for the development process. Testing design ideas rapidly with end users during the design process to adjust the design and usability problems will help to achieve the same look and feel of the visual information in a responsive web environment.

Responsive web usability should consider the different ways of navigating the web site across multiple devices, while still maintaining clear information hierarchy, readability and legibility, and consistency in design styles. A consistent user experience is created through the effective use of visual elements such as the brand logo, colors, images, and a unique design style. In order to create successful responsive web site identity, defining the company's goals and users' goals for the web site with a team and testing the every step with end users are strongly recommended. "Just like corporate identity systems in traditional media, responsive web site identity must be considered critical to an effective branding effort on the web. At the same time, to design effective web site identity systems, a designer must take into consideration the web's unique dynamic and flexible characteristics (Kang and Satterfield, 2010)" for multiple screen sizes and platforms.

FUTURE RESEARCH DIRECTIONS

In this chapter, visual identity for responsive web design is examined through a variety of sources in a literature review. There are many usability

and UX studies for responsive web. However, no study has been conducted to determine the role of web site identity in the effectiveness of responsive web design. Future studies to identify best practices for usability and the effective use of visual elements in the responsive web design would be beneficial to both visual web designer and developers.

KEY TERMS AND DEFINITIONS

Brand Identity: The visual elements and company's identity can distinguish the brand in consumer's mind and create brand identity.

Corporate Identity: Taglines, logos, and marketing elements which could build company's identity and brand image.

Experience Design: The way that the target audience experiences the brand from the first knowledge of the company through the complete consumer process.

Grid: Organizational structure used to create information templates.

Logo: A graphical element composed of a symbol and/or organization name.

Monochromatic: Color schemes uses only one color (hue) with various shades and tints.

Signatures: Combination of a logo mark and a company name.

Visual Identity: Visual elements such as a corporate logo, system elements, color system, typography to build company's identity.

Web Site Mobilization Techniques

John Christopher Sandvig

Western Washington University, USA

INTRODUCTION

The introduction of the first Apple iPhone in January 2007 started a historic shift in web browsing from desktop and laptop computers to smartphones and other mobile digital devices. By 2014 two of the largest global shopping sites, Amazon.com and Target.com, reported that the majority of their traffic originated from mobile devices (Sterling, 2015). During the first quarter of 2015 34% of global e-commerce transactions were conducted via mobile devices (“State of Mobile Commerce,” 2015). The number of smartphone users worldwide is forecast to grow from 2.08 billion in 2016 to 2.5 billion by 2019. Over 36% of the world’s population is projected to use a smartphone by 2018 (Statista, 2016). As the number of smartphone uses grows it is becoming increasingly important that web sites provide a good user experience on mobile devices.

BACKGROUND

Mobile devices have several physical limitations that require the use of special web design techniques to produce a mobile-friendly user interface. These physical limitations include small screens, virtual keyboards, slow download speeds, and high network latency. To accommodate these physical limitations mobile-friendly web sites often display less information than desktop sites, have larger tap targets such as buttons and form fields, use smaller images, and offer fewer navigation options. Sites that are developed primarily for desktop and laptop computers often require mobile users to zoom in and scroll horizontally, providing a poor user experience. Mobile-friendly web sites

are designed to render well on all devices, not just mobile devices.

MOBILIZATION TECHNIQUES

Currently there are three popular techniques for developing mobile-friendly web sites: responsive, dynamic serving, and redirect to separate URL. These techniques are referred to by a variety of names so to avoid confusion this article will adopt the nomenclature utilized in Google’s Mobile Developer Guide (“Mobile SEO Overview,” 2016). All three techniques detect the size of the user’s screen and modify the page content and layout to accommodate the device. The techniques differ in how they detect screen size and the mechanisms by which they modify page content.

Responsive Web Design

The responsive design technique delivers the same content (HTML, CSS, JavaScript, images, etc.) to all devices and “responds” to screen size by modifying the layout. For instance, a page design that utilizes a three column layout on a desktop computer may be displayed as one long vertical column on a mobile device. Tabbed navigation on a desktop computer may be displayed as a hamburger menu on a mobile device, and large images may be reduced in size for mobile devices.

Responsive is a relatively new technique. The phrase “responsive web design” was originally defined by Ethan Marcotte in 2007 (Els, 2015). Marcotte states that web pages should be designed with the flexibility to respond and adapt to the capabilities of various devices. At the time Marcotte proposed this approach CSS did not have the

DOI: 10.4018/978-1-5225-2255-3.ch704

ability to detect screen size but the approach could be implemented using JavaScript. This capability was included in the final recommendations for CSS3 and adopted in 2012 by the World Wide Web Consortium (Hargreaves, 2015). It then took a few years for web browser software to implement new standards and for web site developers to employ the new capabilities in web sites.

CSS media queries have the ability to detect screen size, thus allowing developers to create different layouts for different size screens. For example the following media query located in a site's css file would allow a developer to define styles for devices with screen widths between 320px and 400px.

```
@media screen and (min-device-width:
320px) and (max-width: 400px) {
    /* styles for small screens
go here */
}
```

The responsive technique is often implemented using any one of several open-source grid frameworks. These frameworks provide a basic structure for page layout, eliminating the need for developers to create designs from scratch. There are over two dozen grid frameworks include Bootstrap, Foundation 3, Skeleton, 1140 CSS Grid, and Less Framework 4 (Jain, 2015).

CSS frameworks allow developers to design different layouts for different size screens. For instance, Bootstrap 4.0 defines breakpoints at five different screen widths: extra small (less than 34em), small (34-47em), medium (48-61em), large (62-74em) and extra large (75em and larger) (Oliver 2015). Web designers can then create specific layouts for each of these five screen size ranges. Other styles classes, such as Bootstrap's. hidden-*-up and.hidden-*-down (where * is xs, sm, md, lg, and xl) allow developers to target specific content to different size screens. Many grid frameworks also provide JavaScript files that

work in conjunction with built-in CSS classes to provide dynamic features such as dropdown navigation, breadcrumbs, and hamburger menus (Lambert, 2016).

The responsive mobilization technique can also be implemented using JavaScript. JavaScript is a programming language that is supported by all modern browsers. It has the ability to detect screen sizes and apply formatting styles. For example the following JavaScript would hide an HTML element for screens widths between 320px and 400px.

```
if(screen.width >= 320 && screen.
width <= 400) {
    document.getElementById("nav").
style.display = "none";
}
```

While JavaScript is capable of implementing the responsive technique CSS media queries are designed specifically for page formatting and are easier to implement (Knight, 2011).

Dynamic Serving

The dynamic serving technique sends different page content and layout to different devices. The web server examines information which is contained in the web request and sends content and layout appropriate to the capabilities of the device. The dynamic serving technique has the advantage that it can send assets which are optimized for the device. For instance, if the server detects a mobile device it may send smaller and fewer images, thus reducing data usage and page load time.

To identify the requesting device the dynamic serving technique examines metadata that is included in the headers of each web request. Metadata includes information about the request, such as character encoding, language, cookies, caching, and the user-agent. The user-agent attribute includes information about the user's

browser and operating system. For example, the user-agent data sent from an iPhone 6 contains the following information:

```
user-agent:Mozilla/5.0 (iPhone; CPU
iPhone OS 9_1 like Mac OS X) App-
leWebKit/601.1.46 (KHTML, like
Gecko) Version/9.0 Mobile/13B143 Sa-
fari/601.1
```

A server can examine this data to determine that the requesting device is an iPhone using operating system 9_1. While the user-agent does not specifically include information about the screen size the server can lookup the typical screen sizes for the device and send appropriate content and formatting.

The weakness of the dynamic serving technique is in correctly identifying the user's device ("Mobile SEO Overview," 2016). The technique depends upon the server having a current list of user-agent strings to match against. Given the large number of mobile devices and the frequent introduction of new devices the user-agent lookup tables must be frequently updated. In practice many website administrators do not update the lookup table on a regular basis and servers do not correctly identify devices.

It is also easy for servers to misidentify the requesting device by matching incorrectly. For example, the server may match the word "Android" and determine that the request came from an Android phone when the request actually originated from a Chromebook laptop which also utilizes the Chrome operating system.

Redirect to Separate URL

The third popular mobilization technique redirects mobile devices to a separate URL. The separate URL then delivers content and layout appropriate to mobile devices. This technique is similar to the dynamic serving technique in that it can send images, layout, and other content that is

optimized for mobile devices. Like the dynamic serving technique, this technique depends upon correctly identifying the requesting device from the user-agent string.

Selecting a Mobilization Technique

The responsive technique has the advantage that it is relatively easy to implement. A number of free open-source CSS grid frameworks are available that provide developers with convenient tools for designing pages that render well on all devices. A weakness of the responsive technique is that exactly the same content is delivered to all devices, using excessive amounts of bandwidth and slowing page load times. Mobile layouts often display less content and smaller images than desktop computers and can benefit from using less data and having faster load times, an opportunity that is lost with the responsive technique. A second weakness of the response technique is that the CSS and JavaScript files used by the grid frameworks can be fairly large, using more data and increasing page render time. Despite these disadvantages the responsive technique is Google's recommended design pattern ("Mobile SEO Overview" 2016).

The dynamic server and separate URL techniques both have the advantage of serving content that is optimized to the capabilities of the device. Smaller images and less content can be sent to mobile devices, thus speeding download times and using less data. A recent empirical study of large global e-commerce sites found that sites using the separate URL technique used 67.7% as much data for their mobile sites as for their desktop sites, while dynamic serving used 80.5% as much data (Sandvig, 2016). Surprisingly the reduction in data usage did not translate into faster page render times.

The disadvantage of these techniques is that they both rely upon examining the user-agent string and correctly identifying the device. If this is done incorrectly the techniques may send content and layout that is not appropriate for the device.

A second disadvantage of the redirect to a separate URL technique is that redirecting the browser to a different site increases page load time. The amount of time varies from a fraction of a second to several seconds depending upon network latency, network congestion, and other factors (Doswell, Kendall, Aslam, & Sexton (2015).

The previously mentioned empirical study by Sandvig (2016) explored the utilization of the three techniques on large global e-commerce sites. The study examined the landing pages of Alexa's 527 top global shopping sites. It found that 89.3% of top global shopping sites utilized mobile-friendly designs. The most popular mobile technique was to redirect to a separate URL, utilized by 44.1% of sites, followed by dynamic serving, utilized by 23.8%, and responsive, utilized by 23.0% of sites.

Identifying Mobilization Techniques

A web site's behavior can be used to identify which mobilization technique, if any, is used. Modern desktop browsers, such as Chrome, Firefox, and Internet Explorer have built-in mobile emulators that can be used to compare how a site displays on desktop versus a mobile device. The following sequence of tests can be used to identify a site's mobilization technique or lack of technique. These instructions are specific to the Chrome browser but the steps are similar with other major browsers. Steps to identify a site's mobilization technique:

1. On a desktop computer use the Chrome browser to open the web site being examined.
2. Press the F12 key to open the developer console. In the top left of the developer console is an icon with a small box superimposed over a larger box. This icon toggles the view between desktop and mobile views. Initially it will be in desktop view.
3. **Separate URL Technique:** Click the mobile emulation icon to toggle to mobile view. Also reload the page by clicking the page reload icon left of the site's URL (or press the F5 key). If the address changes to a dif-

ferent URL then the site uses the separate URL mobilization technique. For example, at the time of this writing www.facebook.com changes to m.facebook.com.

4. **No Mobilization Technique:** If the mobile site displays poorly with small text or is too wide for the mobile screen the site is not mobile friendly. At the time of this writing the site discoverelks.org is not mobile friendly.
5. **Responsive Technique:** The layout of responsive sites changes without reloading the page. Click the mobile emulation icon a few times and observe if the page layout changes back and forth between a mobile and desktop layout. If it does then the site utilizes the responsive technique. At the time of this writing site www.wvu.edu uses the responsive technique.
6. **Server Adaptive Technique:** This technique sends different content to the browser depending upon the type of device that made the request. To identify the server adaptive technique we need to see if the content sent to the browser changes between desktop and mobile views. In the Chrome developer console click the network tab (top of window), check the "disable cache" box, and reload the page. At the bottom the developer console the number of requests and the kilobytes (KB) of data downloaded is displayed. Compare these numbers for the desktop and mobile views (remember to reload the page after toggling the view). If they are significantly different the technique is server adaptive. At the time of writing Amazon.com's desktop site made 309 request and transferred 6.1 MB (megabytes) of data and its mobile site made 61 request and transferred 925 KB of data. Because these numbers are significantly different we can conclude that Amazon uses the server adaptive technique. The numbers may changes slightly with each load so it may be necessary to repeat the above steps a few times.

Emerging Mobilization Technique

The limitations of current mobilization techniques have motivated the development of a new approach called Accelerated Mobile Pages (AMP). The open source project was launched February 2016 and is sponsored by Google and Twitter. The goal of AMP is “dramatically improve the performance of the mobile web” (Mizroch, 2015). Usability studies of mobile user have found that the average mobile user will wait only three seconds for a mobile page to load before abandoning the page (Vijayan 2016). AMP is a new web design standard that prioritizes page render speed over other features. It disallows many design elements that slow the rendering of web pages on mobile devices, such as JavaScript code and third-party scripts. It also requires the use of certain design features that allow pages to load more quickly, such as height and width attributes on images. The only JavaScript allowed in AMP pages is the AMP JS library itself. This library optimizes resource loading, provides custom AMP HTML tags, disables slow CSS selectors, and provides other speed optimization features. To further increase speed Google will cache valid AMP pages and serve them directly from its data centers. According to Google AMP pages load on mobile devices in approximately one quarter the time and use about 10% as much data as regular web pages (Vijayan 2016).

To encourage rapid adoption AMP supports have enlisted several major web sites, media outlets, and content management systems to adopt AMP standards. A variety of media outlets including the *New York Times*, BuzzFeed, Twitter, *The Guardian*, Ebay and Vox Media have pledged support for the project (Vanian, 2016).

Web pages that use AMP are identified as such in Google mobile search results as shown in figure 1.

A downside of the AMP standard is that it disallows many rich features that are common on desktop sites. Many publishers that utilize AMP for their mobile sites will likely elect to maintain

Figure 1.

a separate site for desktop users (Vijayan 2016). Maintaining multiple web sites increases expenses and has the other disadvantages discussed earlier for the separate URL mobilization technique.

FUTURE RESEARCH DIRECTIONS

The rapid evolution of mobilization techniques presents researches with a host of research opportunities. While there has been a plethora of research of measuring mobile usability (Coursaris & Kim, 2011; Venkatesh, Ramesh, & Massey, 2003; Kjeldskov & Stage, 2004; Zhang & Adipt, 2005) there is little research on implementing mobilization techniques. Practitioners who are faced with the decision of selecting a mobilization strategy need to guidance to answer the following questions:

- What are the relative implementation and maintenance costs for each mobilization technique?
- Does the technique provide a good user experience for both desktop and mobile users?
- What are the performance tradeoffs between the techniques in terms of speed, reliability, user experience, and costs?
- Which techniques are more popular within different industries and why?
- Which mobilization techniques are growing and which are declining?
- How does an organization's existing infrastructure and human resources impact its choice of mobilization strategy?
- Are new and improved mobilization techniques on the horizon that are going to make existing techniques obsolete?

Several research approaches could be used by researchers to address these issues. Questions relating to implementation and maintenance costs could be answered by surveying webmasters of different organizations in different industries. Webmaster surveys could also be used to evaluate satisfaction with end user experience and reliability. The questions related to technique popularity and performance could be answered by evaluating actual web performance, similar to the survey of large global e-commerce sites by Sandvig (2016). The questions related to infrastructure, human resources, and future directions could be addressed using focus groups of industry experts.

CONCLUSION

The rapid adoption of mobile devices over the past decade has created a need web for mobile-friendly web sites. This article has described the three most popular web mobilization techniques: response, server adaptive, and redirect to a separate URL. All three techniques modify web page content

and layout to accommodate all types of devices, including mobile.

A completely new approach to mobilization, Accelerated Mobile Pages, was introduced in early 2016. While current mobilization techniques utilize standard HTML and CSS to adapt web pages to various screen sizes, AMP utilizes a new technical standard. The new standard consists of a subset of HTML and CSS and utilizes JavaScript to optimize speed performance. While it is too early to know how widely AMP will be adopted it is being widely promoted and several major web publishers are experimenting with it.

KEY TERMS AND DEFINITIONS

CSS: Cascading style sheets is a language used to describe the presentation of a web page. CSS is used to define style attributes such as fonts, colors, spacing, positioning, and backgrounds. CSS works in conjunction with HTML to define and format page content.

HTML: Hypertext markup language is a standard used for describing web page content. HTML elements are delineated by dozens of different tags which are enclosed by angle brackets. For

example, a paragraph of text may be surrounded by paragraph `<p>` `</p>` tags, and an image included using an `<image>` tag. HTML works in conjunction with CSS to define and format page content.

JavaScript: A programming language that is supported by all modern web browsers. It can be used to add dynamic features such as image slide shows, accordion menus, rollover effects, and asynchronous server requests.

Media Queries: A feature of CSS that is used to define different style rules for different media types. Media types include screen, print, and speech. When developing pages that are mobile-friendly media queries are often used to detect screen size and apply styles appropriate to the device.

What Accounts for the Differences in Internet Diffusion Rates Around the World?

W**Ravi Nath***Creighton University, USA***Vasudeva Murthy***Creighton University, USA*

INTRODUCTION

The literature is replete with studies that indicate a strong link between the adoption and use of the Internet and economic growth not only for individual citizens but also for national economies. Despite the irrefutable benefits of the Internet, in many countries around the world, the Internet adoption rates remain low. In Africa, according to the 2015 data, 10.7 percent of the households enjoy Internet access at home and about one individual out of five (20.7%) uses the Internet (International Telecommunications Union (ITU), 2016). In contrast, in Europe, these figures are 82.1% and 77.6%, respectively. Figure 1 clearly highlights the gross disparity that exists between the Internet diffusion rates for the Organization for Economic Cooperation and Development (OECD) and Sub Saharan Africa (SSA) countries. Thus, the question of why do these differences exist is worth investigating. And, an understanding of the factors that promote and/or hamper the adoption of the Internet is warranted as the insights gleaned from this can assist policy makers, economic developmental agencies, and the political leaderships in formulating appropriate strategies and policies.

BACKGROUND

The Internet and the associated technologies are vital in boosting the economic wellbeing of nations and their citizens. Applications such

as e-business, voice over IP (VoIP), mobile commerce, and integrated supply chains have become the primary drivers of the growth of economic activities in many countries (Albirini, 2008; Dedrick, Gurbaxani, & Kraemer, 2003; Kenny, 2003; Koh & Chong, 2002). Further, the Internet is providing revenue-generating and skill-enhancing opportunities to individuals across the globe. For individuals, it avails the opportunities to sell things online, collaborate with others at far-flung places, learn new skills, access data/information quickly, and communicate rapidly (Chavula, 2013; James, 2008; Larson & Murray, 2008; Laguerre, 2013). Adoption and use of the Internet and other technologies have boosted trade and globalization leading to improved GDP (Albirini, 2008; Kuppusamy, M. & Santhapparaj, A.S., 2005; Lawrence, 2002; Raheel, Karim, Saleem & Bharwani, 2012). In fact, the 2015 Global Information Technology Report asserts that digital technologies can boost global economic output and creates new economic opportunities for individuals particularly in countries with very low technology penetration rates. The report also claims that a 10% increase in a country's telecommunications infrastructure boosts the GDP by nearly 2.8 percentage points provided the country first achieved a certain minimum threshold of digitization. The threshold is estimated to be about 24 of the population. The 2013 Global Information Technology Report had claimed that a doubling of mobile data usage increases GDP per capita by ½ a percent point. Accelerated economic growth of

Figure 1. Internet Diffusion rates for OECD and Sub Saharan Africa (SSA) – 1990-2015

India and China in the last decade is also a prime example of how Information and Communication Technologies (ICT) in concert with appropriate economic, intellectual property protection, and infrastructure improvement policies promote rapid economic development (Also see, Global Information Technology Report, 2015).

GLOBAL INTERNET ADOPTION FACTORS

At the national level, there exist many factors that influence the Internet adoption rate. These factors include the availability of reasonably-priced technology/telecommunications infrastructure, access to personal computers, educational and training opportunities for individuals, income levels, innovative capability, culture, competition in the information technology industry, and the availability of local Internet content (Beilock & Dimitrova, 2003; Birba & Diagne, 2012; Chinn & Fairlie, 2007; Choi, Williams & Ha, 2014; Dewan, Ganley & Kraemer, 2010; Dholakia, Dholakia & Kshetri, 2003; Feng, 2015; Galagedarage & Salman, 2015; Huang & Chen, 2010; Kiiski & Pohjola, 2002; McCoy, Cha & Durcikova, 2012; Meijers, 2006; Murthy, 2004; Murthy, Nath & Soleimani, 2015; Nath & Murthy, 2003, 2004;

Ojuloge & Awoleye, 2012; Oyelaran-Oyeyinka & Lal, 2005; Soleimani, 2015; Touray, Saminen & Mursu, 2015; Wunnava & Leiter, 2009). Further, the rule of law (e.g., property rights, strong legal system) governing the country's trading system, government regulations and market liberalization policies, and credible payment systems (e.g., credit cards, digital wallet and cash) are necessary for expanding into mobile and digital commerce.

Human Capital Development Factors

It is virtually impossible to fully reap the benefits of the Internet if people are not able to read or write or have a basic understanding of computers, Internet and their applications. Therefore, an individual has to possess a minimum level of computer/technology and language literacy to use the Internet for beneficial purposes. At the national/regional level, one way to assess this is to consider factors such as:

1. Adult literacy rate
2. Percent of school age children enrolled in schools
3. Per capita spending on education

Many studies including those by Balamoun-Lutz (2003), McCoy, Cha and Durcikova (2012),

Nath and Murthy (2003), Noce and McKeown (2008), and Wunnava and Leiter (2009) have concluded that literacy and tertiary enrollment rates have a strong positive influence on Internet adoption. Also, literate citizens are more accepting of information and communication technology (ICT) innovations. And this results in higher acceptability and utilization of the Internet and its applications in commerce, personal productivity tools, education, health, and social networking.

Technology Factors

As one would expect, a reliable and cost effective network infrastructure is a prerequisite for people to use the Internet. This includes the bandwidth, the number of Internet hosts, the reliability of electric power, and the percent of the population of a nation that have access the Internet. In addition, people who are familiar and comfortable with using other technologies such as a phone, a mobile phone and a personal computer are more likely to adopt and use the Internet. Specific variables that one may consider here are:

1. Number of personal computers per 100 inhabitants.
2. Telephone lines per 100 inhabitants.
3. Cell phone subscribers per 100 inhabitants.
4. Number bandwidth (bits) per capita.
5. Reliability of electrical power.

One key aspect of the new economy is the availability of cost-effective information and communication technologies (ICT) and the above listed items represent leading indicators of ICT (Balioune-Lutz, 2003). Several studies have established that countries with higher availability rates of personal computers, tablets, telephones, and mobile phones, sufficient bandwidth and reliable supply of electricity that powers most ICT devices, also have more Internet users (Nath & Murthy, 2003, 2004; Soleimani, 2015; Wunnava & Leiter, 2009). Further, the availability of online digital content, its quality and relevance also seem

to play a role on the adoption of the Internet (Viard and Economides, 2015).

Economic Factors

How expensive is it to get online? If this cost is prohibitively high relative to the income, then the Internet penetration rate is bound to be low. The two variables that are relevant here are:

1. Real Gross domestic product per capita (in US purchasing parity \$).
2. Average monthly cost of 20 hours of Internet access.

Kiiski and Pohjola (2002), and McCoy, Cha and Durcikova (2012), found that, across countries, GDP per capita and Internet access costs were good predictors of the growth of the Internet. Further, Nath and Murthy (2004) using data from 62 countries, demonstrated that higher “average monthly cost of 20 hours of Internet access” had a significant negative impact on the Internet adoption rates.

Political Factors

A nation’s government policies and regulations are also important in promoting Internet adoption among its population. Many nations restrict the use of the Internet (e.g., China, Iran and North Korea). Also, the economic policies of the government can affect the degree to which its citizens use the Internet. Variables that measure “political and economic” policies include:

1. **Economic Freedom Index (EFI):** Beach and O’Driscoll (2003) define this index as the “.... absence of government coercion or constraint on the production, distribution, or consumption of goods and services beyond the extent necessary for citizens to protect and maintain liberty itself.” This index aggregates several factors covering broad issues such as corruption, non-tariff

barriers to trade, the fiscal burden of government, the rule of law and efficiency of the judiciary, regulatory hurdles for businesses, labor market restriction, and black market activities. Complete details regarding the development and description of this index can be found in Beach and O'Driscoll (2003). The values of EFI can vary from 1 to 5. A value of 1 indicates set of national policies that promote economic freedom and a value of 5 signifies policies that are least conducive to economic freedom.

2. **Innovation Capability of the Country:** This variable is calculated as the product of the number of patents granted per million inhabitants and gross tertiary enrollment rate. Note that the number of patents reflects the nation's innovation intensity and the enrollment rates denote the degree of investment in human capital. Thus, this measure reflects a country's capability, ability to provide a conducive environment for augmenting technological advance and its capacity for innovation in technologies and products (McArthur & Sachs, 2000).

In a study of the adoption of the Internet across countries, Nath and Murthy (2003) have shown that both the economic freedom index and the innovation capability of a country play a positive role towards the adoption of the Internet. These findings have been further supported by Balamoun-Lutz (2003) and Nath and Murthy (2004). Also, Choi, Williams & Ha (2014) report that the State influence – policies that promote the Internet and education – have significant impact on the diffusion of the broadband Internet.

Cultural Factors

Cultural factors do impact the rate of diffusion of the Internet. Culture is defined as: "the collective programming of the mind which distinguishes

the members of one human group from another (Hofstede, 1991, p.5)." In his book titled *Culture's Consequences*, Hofstede (1980) suggested four dimensions of culture.

1. **Power Distance (PD):** Power distance is defined as "the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally" (Hofstede, 1991, p.27). In cultures with high power distance, decisions are centralized and subordinates are often fearful of disagreeing with their superiors. On the other hand, cultures with low power distance are more participative and have less tolerance for the lack of autonomy. In a society with low power distance, we expect people to be more innovative and willing to try new things.
2. **Individualism vs. Collectivism (IND):** This dimension relates to the way people live together. Individualism "pertains to societies in which the ties between individuals are loose: everyone is expected to look after himself or herself and his or her immediate family" (Hofstede, 1991, p.51). On the other hand, collectivism "pertains to societies in which people from birth onwards are integrated into strong, cohesive groups, which throughout people's lifetime continue to protect them in exchange for unquestioning loyalty" (Hofstede, 1991). Cultures with high individualism value personal time and achievement. Such societies are expected to be more innovative and open to new ideas.
3. **Uncertainty Avoidance (UA):** Uncertainty avoidance refers to "the extent to which the members of a culture feel threatened by uncertain or unknown situations" (Hofstede, 1991, p. 113). A culture high in uncertainty avoidance is rule oriented, has less tolerance for opinions and behaviors different from its own, and avoids taking risks. There is also

resistance to change. Cultures with high uncertainty avoidance are expected to be less innovative and less accepting of new things.

4. **Masculinity vs. Femininity (MAS):** This is possibly the most controversial dimension of culture advocated by Hofstede. In highly masculine cultures “men are supposed to be assertive, tough and focused on material success; women are supposed to be more modest, tender and concerned with the quality of life” (Hofstede et al., 1998). The more modern and popular perspective on this dimension is to view the masculine and feminine culture in terms of competitiveness and material success versus nurturing behavior and quality of life, as opposed to gender roles for the sexes.

There is considerable evidence supporting that cultural factors influence the use of various technological innovations. Yaveroglu and Donthu (2002) indicate that the use of cell phones, home computers, and microwave ovens is high in countries with low power distance, low uncertainty avoidance, and high individualism. Yenyurt and Townsend (2003) investigated the role that culture plays in the acceptance of new products. Their findings indicate that lower acceptance of new products is related to power distance and uncertainty avoidance. With respect to the adoption of Enterprise Resource Planning (ERP) software, national culture is shown to have a significant influence on its adoption rate (van Everdingen & Waarts, 2003). Cultural considerations even play a role in how information systems, in general, are designed, implemented, and used (Gallupe & Tan, 1999; Nelson & Clark, 1994; Watson, Ho, & Raman, 1994; Straub, 1994; Montealegre, 1997; Jarvenpaa & Leidner, 1998; Thatcher, Srite, Stepina, Liu, 2003). With respect to the role of culture on Internet diffusion, Nath and Murthy (2004) have shown that “uncertainty avoidance” and “masculinity” are positively associated with the diffusion of the Internet.

Individual User Factors

An individual user's needs and cognition are important in the Internet adoption decision. Zhu and He (2002) assert that there are three user cognition factors that one needs to consider:

1. **Perceived Characteristics of the Internet:** This includes perceived ease of use, compatibility, and the perceived advantage of the Internet.
2. **Perceived Popularity of the Internet:** This refers to the percent of Internet users among the user's close network (family, friends, and acquaintances).
3. **Perceived Need for the Internet:** To what extent the user thinks he/she needs the Internet for things like the news, information, entertainment, etc.

Using surrogate variables such as literacy ratios, number of PCs, number of TV sets (discussed above in other factors) for McCoy, Cha, and Durcikova (2012) show that user cognitive factors are important in the diffusion of the Internet.

FUTURE RESEARCH DIRECTIONS

The future for the Internet adoption and its use is very promising. First, the broadband access to the Internet will increase rapidly allowing people very high-speed access to the Internet. Consequently, it will be possible for users to download rich content at a very high speed. Second, Internet access costs will decline due to global competition and economic reforms taking place in countries around the world. Third, as many nations become receptive to economic reforms and provide additional economic freedom opportunities to its citizens, entrepreneurship will thrive, incomes will rise, information economies will thrive and more people will use the Internet and become fully vested in the information economy. Fourth, smart phones will play an increasingly important

role in providing Internet access to citizens around the world in anytime, anywhere environment. Further, mobile phone access to the Internet will yield unprecedented economic benefits to citizens at the “bottom of the pyramid” around the world. For example, mobile money services have proliferated in Sub-Saharan Africa providing financial services to millions of previously unbanked citizens (The mobile economy: Sub-Saharan Africa, 2014). Finally, individual privacy issues will become more prominent as there will be fierce debates on striking a balance between protecting individual privacy and going fully-digital via the Internet, mobile phone, and other accompanying technologies. However, in spite of these limiting concerns, people and governments around the world will increasingly look to the Internet to better their lives.

CONCLUSION

A clear and vivid understanding of the factors that determine the adoption of the Internet is important for researchers, practitioners, and policy makers. Researchers who wish to study international information technology issues and their economic implications must be cognizant of these factors in determining Internet user behaviors and technology adoption patterns. Also, an understanding of inter-country differences with respect to these adoption factors can improve IT/IS research design strategies and enhance the conduct of global information technology research studies.

At the national level, policy makers, political leadership, and think tanks can benefit by incorporating the insights gleaned from this article into their deliberations and policy plans – leading to more informed macro-level strategic policies. Without a cohesive and carefully crafted national development strategies and policies, nations are likely to miss out on the tremendous benefits the Internet has to offer to its citizens and national development.

KEY TERMS AND DEFINITIONS

Economic Freedom Index: A measure of the absence of government constraints on the economic activities of a nation.

Hofstede's Cultural Dimensions: Four factors proposed by Hofstede along which cultures might differ.

Internet Adoption Rate: Percent of population of a country having access to the Internet.

Power Distance (PD): A measure of the unequal distribution of power in a society. Cultures with high power distance are centralized whereas cultures with low power distance are more participative and individuals like more autonomy.

Uncertainty Avoidance (UA): A measure of how well a culture accepts uncertainty. A culture with high uncertainty avoidance is mostly rule oriented and is less tolerant of divergent opinions and behaviors.
